Puppet Enterprise 2019.8.1
Contents

Welcome to Puppet Enterprise® 2019.8.1................................................................. 12
   PE architecture.................................................................................................. 12
   The master and compilers.................................................................................. 13
   The Puppet agent............................................................................................... 14
   Console services................................................................................................. 15
   Code Manager and r10k.................................................................................... 17
   Orchestration services....................................................................................... 17
   PE databases...................................................................................................... 17
   Security and communications.......................................................................... 18
   Component versions in recent PE releases...................................................... 19
      Master and agent compatibility.................................................................. 20
      Task compatibility....................................................................................... 21
   PE and FIPS compliance................................................................................... 21
   Getting support................................................................................................. 22
      Puppet Enterprise support life cycle............................................................... 22
      Support portal.............................................................................................. 22
      Puppet metrics collector............................................................................. 22
      PE support script......................................................................................... 23
      Community support..................................................................................... 30
   Using the PE docs............................................................................................. 30
      Archived PE docs........................................................................................ 30
      Usage notes for example commands.......................................................... 31
   Puppet platform documentation for PE........................................................ 31
   API index.......................................................................................................... 33

Release notes.......................................................................................................... 35
   PE release notes............................................................................................... 36
      PE 2019.8.1.................................................................................................. 36
      PE 2019.8.................................................................................................... 39
   PE known issues............................................................................................... 41
      Installation and upgrade known issues......................................................... 41
      Disaster recovery known issues.................................................................. 43
      FIPS known issues..................................................................................... 43
      Configuration and maintenance known issues............................................ 43
      Orchestration services known issues......................................................... 44
      Code management known issues............................................................... 44
      SSL and certificate known issues............................................................... 46
   What's new since PE 2018.1.............................................................................. 46

Getting started with Puppet Enterprise................................................................. 52
   Install PE......................................................................................................... 52
   Install PE console............................................................................................. 53
   Log into the PE console................................................................................... 53
   Check the status of your master...................................................................... 53
   Add nodes to the inventory.............................................................................. 54
   Add agent nodes............................................................................................. 54
   Add agentless nodes....................................................................................... 54

pe | Contents | ii
Installing...................................................................................................................70

Add code and set up Code Manager......................................................................55
Create a control repo from the Puppet template...................................................55
Configure Code Manager.......................................................................................57
Deploy your code....................................................................................................58

Manage Apache configuration on *nix targets.......................................................64
Add a module........................................................................................................64
Configure your desired state................................................................................65
Organize webserver configurations with roles and profiles.................................66

Next steps.............................................................................................................70

Installing...................................................................................................................70

Choosing an architecture.......................................................................................71
System requirements..............................................................................................73
  Hardware requirements.......................................................................................73
  Supported operating systems.............................................................................77
  Supported browsers............................................................................................83
  System configuration..........................................................................................83
What gets installed and where?.............................................................................89
  Software components installed.........................................................................89
  Executable binaries and symlinks installed.......................................................91
  Modules and plugins installed...........................................................................91
  Configuration files installed.............................................................................91
  Tools installed....................................................................................................92
  Databases installed...........................................................................................92
  Services installed..............................................................................................92
  User and group accounts installed...............................................................93
  Log files installed.............................................................................................93
  Certificates installed........................................................................................95
  Secret key file installed....................................................................................95
Installing Puppet Enterprise....................................................................................95
  Install PE.........................................................................................................96
  Verify the installation package........................................................................96
  Configuration parameters and the pe.conf file..............................................97
Purchasing and installing a license key.................................................................104
  Getting a license...............................................................................................105
  Install a license key.........................................................................................105
  View license details for your environment......................................................105
Installing agents..................................................................................................106
  Using the install script.....................................................................................106
  Install *nix agents...........................................................................................109
  Install Windows agents...................................................................................113
  Install macOS agents......................................................................................120
  Install non-root agents...................................................................................120
  Managing certificate signing requests...........................................................124
  Configuring agents.........................................................................................124
Installing compilers..............................................................................................125
  How compilers work.......................................................................................125
  Using load balancers with compilers...........................................................126
  Install compilers.............................................................................................127
  Configure compilers.......................................................................................128
Configuring Puppet Enterprise ........................................................................... 150
Upgrading .............................................................................................................. 138
Configuring and tuning security settings ......................................................................................................... 161
Configuring and tuning the console ................................................................................................................. 158
Methods for configuring Puppet Enterprise ..................................................................................................... 151
Configure settings using the console................................................................. 151
Configure settings with Hiera............................................................................ 152
Configure settings in pe.conf ............................................................................. 153
Configuring and tuning Puppet Server................................................................ 153
Tune the maximum number of JRuby instances...................................................... 154
Tune the maximum requests per JRuby instance.................................................... 154
Tune the reserved_code_cache............................................................................ 155
Tune the Ruby load path..................................................................................... 155
Tune the multithreaded server setting................................................................. 155
Enable or disable cached data when updating classes....................................... 155
Change the environment_timeout setting.......................................................... 156
Add certificates to the puppet-admin certificate whitelist................................. 156
Disable update checking.................................................................................... 156
Puppet Server configuration files......................................................................... 157
pe-puppet-server.conf settings........................................................................... 157
Configuring and tuning the console..................................................................... 158
Configure the PE console and console-services................................................ 158
Manage the HTTPS redirect................................................................................ 160
Tuning the PostgreSQL buffer pool size.............................................................. 160
Enable data editing in the console....................................................................... 161
Add custom PQL queries to the console.............................................................. 161
Configuring and tuning security settings............................................................ 161
Configure cipher suites...................................................................................... 162
Configure SSL protocols.................................................................................... 162
Convert existing compilers.................................................................................. 129
Installing PE client tools.................................................................................... 129
Supported PE client tools operating systems....................................................... 130
Install PE client tools on a managed workstation.............................................. 131
Install PE client tools on an unmanaged workstation......................................... 131
Configuring and using PE client tools............................................................... 132
Installing external PostgreSQL.......................................................................... 133
Install standalone PE-PostgreSQL....................................................................... 134
Install unmanaged PostgreSQL.......................................................................... 134
Uninstalling.......................................................................................................... 136
Uninstall infrastructure nodes............................................................................ 136
Uninstall agents.................................................................................................. 137
Uninstaller options............................................................................................. 138
Upgrading........................................................................................................... 138
Upgrading Puppet Enterprise................................................................................ 138
Upgrading agents............................................................................................... 145
Upgrade agents using the puppet_agent module.............................................. 146
Upgrade agents using a script............................................................................ 147
Upgrade agents without internet access............................................................ 148
Upgrading the agent independent of PE............................................................ 149
Install unmanaged PostgreSQL.......................................................................... 134
Install standalone PE-PostgreSQL....................................................................... 134
Installing PE client tools.................................................................................... 129
Installing external PostgreSQL.......................................................................... 133
Uninstalling.......................................................................................................... 136
Configuring and tuning security settings............................................................ 161
Configuring and tuning the console..................................................................... 158
Methods for configuring Puppet Enterprise ..................................................................................................... 151
Configure settings using the console................................................................. 151
Configure settings with Hiera............................................................................ 152
Configure settings in pe.conf ............................................................................. 153
Configuring and tuning Puppet Server................................................................ 153
Tune the maximum number of JRuby instances...................................................... 154
Tune the maximum requests per JRuby instance.................................................... 154
Tune the reserved_code_cache............................................................................ 155
Tune the Ruby load path..................................................................................... 155
Tune the multithreaded server setting................................................................. 155
Enable or disable cached data when updating classes....................................... 155
Change the environment_timeout setting.......................................................... 156
Add certificates to the puppet-admin certificate whitelist................................. 156
Disable update checking.................................................................................... 156
Puppet Server configuration files......................................................................... 157
pe-puppet-server.conf settings........................................................................... 157
Configuring and tuning the console..................................................................... 158
Configure the PE console and console-services................................................ 158
Manage the HTTPS redirect................................................................................ 160
Tuning the PostgreSQL buffer pool size.............................................................. 160
Enable data editing in the console....................................................................... 161
Add custom PQL queries to the console.............................................................. 161
Configuring and tuning security settings............................................................ 161
Configure cipher suites...................................................................................... 162
Configure SSL protocols.................................................................................... 162
Convert existing compilers.................................................................................. 129
Installing PE client tools.................................................................................... 129
Supported PE client tools operating systems....................................................... 130
Install PE client tools on a managed workstation.............................................. 131
Install PE client tools on an unmanaged workstation......................................... 131
Configuring and using PE client tools............................................................... 132
Installing external PostgreSQL.......................................................................... 133
Install standalone PE-PostgreSQL....................................................................... 134
Install unmanaged PostgreSQL.......................................................................... 134
Uninstalling.......................................................................................................... 136
Uninstall infrastructure nodes............................................................................ 136
Uninstall agents.................................................................................................. 137
Uninstaller options............................................................................................. 138
Upgrading........................................................................................................... 138
Upgrading Puppet Enterprise................................................................................ 138
Upgrading agents............................................................................................... 145
Upgrade agents using the puppet_agent module.............................................. 146
Upgrade agents using a script............................................................................ 147
Upgrade agents without internet access............................................................ 148
Upgrading the agent independent of PE............................................................ 149
Install unmanaged PostgreSQL.......................................................................... 134
Install standalone PE-PostgreSQL....................................................................... 134
Installing PE client tools.................................................................................... 129
Installing external PostgreSQL.......................................................................... 133
Uninstalling.......................................................................................................... 136
Configuring and tuning security settings............................................................ 161
Configuring and tuning the console..................................................................... 158
Methods for configuring Puppet Enterprise ..................................................................................................... 151
Configure settings using the console................................................................. 151
Configure settings with Hiera............................................................................ 152
Configure settings in pe.conf ............................................................................. 153
Configuring and tuning Puppet Server................................................................ 153
Tune the maximum number of JRuby instances...................................................... 154
Tune the maximum requests per JRuby instance.................................................... 154
Tune the reserved_code_cache............................................................................ 155
Tune the Ruby load path..................................................................................... 155
Tune the multithreaded server setting................................................................. 155
Enable or disable cached data when updating classes....................................... 155
Change the environment_timeout setting.......................................................... 156
Add certificates to the puppet-admin certificate whitelist................................. 156
Disable update checking.................................................................................... 156
Puppet Server configuration files......................................................................... 157
pe-puppet-server.conf settings........................................................................... 157
Configuring and tuning the console..................................................................... 158
Configure the PE console and console-services................................................ 158
Manage the HTTPS redirect................................................................................ 160
Tuning the PostgreSQL buffer pool size.............................................................. 160
Enable data editing in the console....................................................................... 161
Add custom PQL queries to the console.............................................................. 161
Configuring and tuning security settings............................................................ 161
Configure cipher suites...................................................................................... 162
Configure SSL protocols.................................................................................... 162
Configure RBAC and token-based authentication settings..............................................................163
Configuring and tuning PuppetDB........................................................................................................163
Configure agent run reports.....................................................................................................................164
Configure command processing threads.................................................................................................164
Configure how long before PE stops managing deactivated nodes....................................................164
Change the PuppetDB user password....................................................................................................165
Configure excluded facts............................................................................................................................165
Configuring and tuning orchestration.....................................................................................................165
Configure the orchestrator and pe-orchestration-services......................................................................166
Configure the PXP agent..............................................................................................................................167
Correct ARP table overflow......................................................................................................................167
Configuring proxies.....................................................................................................................................168
  Downloading agent installation packages through a proxy.................................................................168
  Setting a proxy for agent traffic...........................................................................................................168
  Setting a proxy for Code Manager traffic............................................................................................169
Configuring Java arguments....................................................................................................................169
  Increase the Java heap size for PE Java services................................................................................170
  Disable Java garbage collection logging..........................................................................................171
Configuring ulimit for PE services.........................................................................................................171
  Configure ulimit for PE services........................................................................................................171
Tuning standard installations..................................................................................................................172
  Master tuning....................................................................................................................................173
  Compiler tuning...................................................................................................................................174
  Using the puppet infrastructure tune command..............................................................................175
Writing configuration files......................................................................................................................175
  Configuration file syntax...................................................................................................................175
Analytics data collection..........................................................................................................................176
  What data does Puppet Enterprise collect?.......................................................................................176
  Opt out during the installation process.............................................................................................180
  Opt out after installing.........................................................................................................................180
Static catalogs in Puppet Enterprise....................................................................................................180
  Enabling static catalogs.....................................................................................................................180
  Disabling static catalogs globally with Hiera....................................................................................182
  Using static catalogs without file sync..............................................................................................182

Configuring disaster recovery...............................................................................................................183
  Disaster recovery..............................................................................................................................183
  Disaster recovery architecture..........................................................................................................183
  What happens during failovers..........................................................................................................184
  System and software requirements for disaster recovery...............................................................184
  Classification and software requirements for disaster recovery....................................................186
  Load balancer timeout in disaster recovery installations...............................................................187
Configure disaster recovery...................................................................................................................187
  Provision and enable a replica.........................................................................................................187
  Promote a replica..............................................................................................................................190
  Enable a new replica using a failed master.......................................................................................190
  Forget a replica................................................................................................................................191
  Reinitialize a replica..........................................................................................................................191

Accessing the console...........................................................................................................................191
  Reaching the console........................................................................................................................192
  Accepting the console's certificate......................................................................................................192
  Logging in..........................................................................................................................................192
  Generate a user password reset token...............................................................................................192
## Managing access

User permissions and user roles................................................................. 194
Structure of user permissions................................................................. 194
User permissions.................................................................................. 194
Working with node group permissions.................................................. 198
Best practices for assigning permissions................................................. 199
Creating and managing local users and user roles.................................... 199
Create a new user.................................................................................. 199
Give a new user access to the console................................................... 200
Create a new user role......................................................................... 200
Assign permissions to a user role........................................................ 200
Add a user to a user role...................................................................... 200
Remove a user from a user role........................................................... 201
Revoke a user’s access.......................................................................... 201
Delete a user......................................................................................... 201
Delete a user role................................................................................ 201
Connecting external directory services to PE.......................................... 201
Connect to an external directory service.............................................. 202
External directory settings..................................................................... 202
Verify directory server certificates....................................................... 206
Enable custom password policies through LDAP.................................... 206
Working with user groups from an external directory service................. 206
Import a user group from an external directory service.......................... 207
Assign a user group to a user role........................................................ 207
Delete a user group............................................................................. 207
Removing a remote user’s access to PE................................................ 207
Token-based authentication.................................................................... 208
Configure puppet-access...................................................................... 208
Generate a token using puppet-access.................................................. 209
Generate a token using the API endpoint.............................................. 210
Generate a token for use by a service.................................................... 211
Change the token’s default lifetime....................................................... 211
Setting a token-specific lifetime.......................................................... 212
Change account expiration settings...................................................... 212
Set a token-specific label.................................................................... 213
View token activity................................................................................ 213
Revoking a token.................................................................................. 213
Delete a token file................................................................................ 213
RBAC API v1.......................................................................................... 213
Endpoints.............................................................................................. 214
Forming RBAC API requests................................................................. 215
Users endpoints..................................................................................... 216
User group endpoints.......................................................................... 220
User roles endpoints............................................................................. 223
Permissions endpoints......................................................................... 226
Token endpoints...................................................................................... 228
Directory service endpoints................................................................... 230
Password endpoints.............................................................................. 232
RBAC service errors............................................................................. 234
Configuration options.......................................................................... 236
RBAC API v2.......................................................................................... 238
Tokens endpoints................................................................................... 238
Activity service API.......................................................................................................................... 242
Forming activity service API requests.............................................................................................. 242
Event types reported by the activity service......................................................................................... 243
Events endpoints.................................................................................................................................. 246

**Inspecting your infrastructure** ........................................................................................................ 249

Monitoring infrastructure state............................................................................................................. 249
  - Node run statuses............................................................................................................................ 249
  - Filtering nodes on the Status page .................................................................................................. 251
  - Filtering nodes in your node list...................................................................................................... 253
  - Monitor PE services......................................................................................................................... 253
Viewing and managing packages............................................................................................................ 254
  - Enable package data collection........................................................................................................ 255
  - View and manage package inventory.............................................................................................. 255
  - View package data collection metadata......................................................................................... 255
  - Disable package data collection....................................................................................................... 256
Infrastructure reports.............................................................................................................................. 256
  - Working with the reports table........................................................................................................ 256
  - Filtering reports................................................................................................................................ 257
  - Working with individual reports...................................................................................................... 258
Analyzing changes across Puppet runs.................................................................................................. 260
  - What is an event?.............................................................................................................................. 260
  - Event types....................................................................................................................................... 260
  - Working with the Events page......................................................................................................... 261
Collecting value analytics......................................................................................................................... 262
  - GET /api/reports/value...................................................................................................................... 262
Viewing and managing Puppet Server metrics........................................................................................ 266
  - Getting started with Graphite............................................................................................................ 266
  - Available Graphite metrics.............................................................................................................. 270
Status API............................................................................................................................................. 274
  - Authenticating to the status API....................................................................................................... 275
  - Forming requests to the status API................................................................................................... 275
  - JSON endpoints............................................................................................................................... 276
  - Activity service plaintext endpoints................................................................................................. 278
  - Metrics endpoints............................................................................................................................ 279
  - The metrics API.............................................................................................................................. 285

**Managing nodes** .......................................................................................................................... 287

Adding and removing agent nodes...................................................................................................... 288
  - Managing certificate signing requests............................................................................................ 288
  - Remove agent nodes........................................................................................................................ 289
Adding and removing agentless nodes.................................................................................................. 290
  - Add agentless nodes to the inventory............................................................................................... 290
  - Transport configuration options....................................................................................................... 291
  - Add devices to the inventory............................................................................................................ 292
  - Remove agentless nodes and devices from the inventory............................................................... 292
How nodes are counted.......................................................................................................................... 293
Running Puppet on nodes....................................................................................................................... 294
  - Running Puppet with the orchestrator............................................................................................... 294
  - Running Puppet with SSH................................................................................................................ 294
  - Running Puppet from the console..................................................................................................... 295
  - Activity logging on console Puppet runs.......................................................................................... 295
  - Troubleshooting Puppet run failures................................................................................................ 295
Grouping and classifying nodes............................................................................................................. 296
How node group inheritance works........................................................................................................ 296
Best practices for classifying node groups.......................................................................................... 296
Create node groups................................................................................................................................... 296
Add nodes to a node group.................................................................................................................. 297
Declare classes.......................................................................................................................................... 299
Enable data editing in the console........................................................................................................... 300
Define data used by node groups.......................................................................................................... 300
View nodes in a node group.................................................................................................................. 302
Making changes to node groups............................................................................................................ 303
Edit or remove node groups.................................................................................................................. 303
Remove nodes from a node group.......................................................................................................... 303
Remove classes from a node group........................................................................................................ 303
Edit or remove parameters..................................................................................................................... 304
Edit or remove variables........................................................................................................................ 304
Environment-based testing................................................................................................................... 304
Test and promote a parameter.............................................................................................................. 304
Test and promote a class........................................................................................................................ 304
Testing code with canary nodes using alternate environments........................................................ 304
Preconfigured node groups................................................................................................................ 305
All Nodes node group........................................................................................................................... 305
Infrastructure node groups.................................................................................................................. 305
Environment node groups.................................................................................................................... 308
Managing Windows nodes.................................................................................................................. 308
Using the Windows module pack......................................................................................................... 308
Managing Windows configurations...................................................................................................... 324
Designing system configs: roles and profiles......................................................................................... 333
The roles and profiles method................................................................................................................ 333
Roles and profiles example..................................................................................................................... 336
Designing advanced profiles................................................................................................................ 338
Designing convenient roles.................................................................................................................. 355
Node classifier API v1............................................................................................................................ 358
Forming node classifier requests......................................................................................................... 359
Groups endpoint....................................................................................................................................... 361
Groups endpoint examples.................................................................................................................... 378
Classes endpoint...................................................................................................................................... 380
Classification endpoint.......................................................................................................................... 382
Commands endpoint............................................................................................................................... 392
Environments endpoint.......................................................................................................................... 393
Nodes check-in history endpoint........................................................................................................... 394
Group children endpoint....................................................................................................................... 397
Rules endpoint........................................................................................................................................ 401
Import hierarchy endpoint...................................................................................................................... 402
Last class update endpoint..................................................................................................................... 403
Update classes endpoint........................................................................................................................ 403
Validation endpoints............................................................................................................................... 404
Node classifier errors.............................................................................................................................. 407
Node classifier API v2............................................................................................................................ 408
Classification endpoint.......................................................................................................................... 408
Node inventory API.................................................................................................................................. 411
Node inventory API: forming requests................................................................................................... 411
POST /command/create-connection..................................................................................................... 412
POST /command/delete-connection.................................................................................................... 415
Command endpoint error responses.................................................................................................... 416
GET /query/connections......................................................................................................................... 417
POST /query/connections........................................................................................................................ 419
Query endpoint error responses............................................................................................................ 421
Managing patches................................................................................................................................. 421
  Configuring patch management........................................................................................................... 422
  Patch management OS compatibility.................................................................................................. 422
  Where patch information comes from............................................................................................... 422
  Create a node group for nodes under patch management................................................................. 423
  Specify patching parameters............................................................................................................... 423
Patching nodes......................................................................................................................................... 427
  Patch nodes........................................................................................................................................ 427

Orchestrating Puppet, tasks, and plans....................................................................................................... 428
  Running jobs with Puppet orchestrator................................................................................................ 429
  Puppet orchestrator technical overview.............................................................................................. 429
  Configuring Puppet orchestrator......................................................................................................... 431
    Orchestration services settings........................................................................................................... 431
    Setting PE RBAC permissions and token authentication for orchestrator........................................ 434
    Orchestrator configuration files........................................................................................................ 435
    PE Bolt services configuration........................................................................................................... 436
    PE ACE services configuration.......................................................................................................... 437
    Disabling application management or orchestration services........................................................... 438
    Direct Puppet: a workflow for controlling change............................................................................ 438
      Direct Puppet workflow................................................................................................................... 438
    Running Puppet on demand............................................................................................................... 441
      Running Puppet on demand from the console................................................................................ 441
      Running Puppet on demand from the CLI....................................................................................... 447
      Running Puppet on demand with the API...................................................................................... 455
  Tasks and plans in PE............................................................................................................................ 458
    Installing tasks and plans................................................................................................................. 459
    Running tasks in PE........................................................................................................................ 460
    Running plans in PE.......................................................................................................................... 472
  Writing tasks.......................................................................................................................................... 477
    Secure coding practices for tasks.................................................................................................... 478
    Naming tasks.................................................................................................................................... 480
    Sharing executables.......................................................................................................................... 481
    Sharing task code............................................................................................................................. 482
    Writing remote tasks........................................................................................................................ 484
    Defining parameters in tasks........................................................................................................... 485
    Returning errors in tasks.................................................................................................................. 486

Welcome to Puppet Enterprise® 2019.8.1

Puppet Enterprise (PE) helps you be productive, agile, and collaborative while managing your IT infrastructure. PE combines a model-driven approach with imperative task execution so you can effectively manage hybrid infrastructure across its entire lifecycle. PE provides the common language that all teams in an IT organization can use to successfully adopt practices such as version control, code review, automated testing, continuous integration, and automated deployment.

PE architecture

Puppet Enterprise (PE) is made up of various components and services including the master and compilers, the Puppet agent, console services, Code Manager and r10k, orchestration services, and databases.

The following diagram shows the architecture of a typical PE installation.
Related information

Component versions in recent PE releases on page 19
These tables show which components are in Puppet Enterprise (PE) releases, covering recent long-term supported (LTS) releases. To see component version tables for a release that has passed its support phase, switch to the docs site for that release.

The master and compilers

The Puppet master is the central hub of activity and process in Puppet Enterprise. This is where code is compiled to create agent catalogs, and where SSL certificates are verified and signed.

PE infrastructure components are installed on a single node: the master. The master always contains a compiler and a Puppet Server. As your installation grows, you can add additional compilers to distribute the catalog compilation workload.

Each compiler contains the Puppet Server, the catalog compiler, and an instance of file sync.
**Puppet Server**

Puppet Server is an application that runs on the Java Virtual Machine (JVM) on the master. In addition to hosting endpoints for the certificate authority service, it also powers the catalog compiler, which compiles configuration catalogs for agent nodes, using Puppet code and various other data sources.

**Catalog compiler**

To configure a managed node, the agent uses a document called a catalog, which it downloads from the master or a compiler. The catalog describes the desired state for each resource that should be managed on the node, and it can specify dependency information for resources that should be managed in a certain order.

**File sync**

File sync keeps your code synchronized across multiple compilers. When triggered by a web endpoint, file sync takes changes from the working directory on the master and deploys the code to a live code directory. File sync then deploys that code to any compilers, ensuring that all masters in a multi-master configuration are kept in sync, and that your code is deployed only when it's ready.

**Certificate Authority**

The internal certificate authority (CA) service accepts certificate signing requests (CSRs) from nodes, serves certificates and a certificate revocation list (CRL) to nodes, and optionally accepts commands to sign or revoke certificates.

The CA service uses `.pem` files in the standard `ssldir` to store credentials. You can use the `puppetserver ca` command to interact with these credentials, including listing, signing, and revoking certificates.

**Note:** Depending on your architecture and security needs, the CA can be hosted either on the master or on its own node. The CA service on compilers is configured, by default, to proxy CA requests to the CA.

**Related information**

- **Hardware requirements** on page 73
  These hardware requirements are based on internal testing at Puppet and are meant only as guidelines to help you determine your hardware needs.
- **Installing compilers** on page 125
  As your Puppet Enterprise infrastructure scales up to 4,000 nodes and beyond, add load-balanced compilers to your installation to increase the number of agents you can manage.
- **About file sync** on page 635
  File sync helps Code Manager keep your Puppet code synchronized across multiple masters.

**The Puppet agent**

Managed nodes run the Puppet agent application, usually as a background service. The master and any compilers also run a Puppet agent.

Periodically, the agent sends facts to a master and requests a catalog. The master compiles the catalog using several sources of information, and returns the catalog to the agent.

After it receives a catalog, the agent applies it by checking each resource the catalog describes. If it finds any resources that are not in their desired state, it makes the changes necessary to correct them. (Or, in no-op mode, it reports on what changes would have been made.)

After applying the catalog, the agent submits a report to its master. Reports from all the agents are stored in PuppetDB and can be accessed in the console.

Puppet agent runs on *nix and Windows systems.

- **Puppet Agent on *nix Systems**
- **Puppet Agent on Windows Systems**
**Facter**

Facter is the cross-platform system profiling library in Puppet. It discovers and reports per-node facts, which are available in your Puppet manifests as variables.

Before requesting a catalog, the agent uses Facter to collect system information about the machine it’s running on.

For example, the fact `os` returns information about the host operating system, and `networking` returns the networking information for the system. Each fact has various elements to further refine the information being gathered. In the `networking` fact, `networking.hostname` provides the hostname of the system.

Facter ships with a built-in list of core facts, but you can build your own custom facts if necessary.

You can also use facts to determine the operational state of your nodes and even to group and classify them in the NC.

**Console services**

The console services includes the console, role-based access control (RBAC) and activity services, and the node classifier.

**The console**

The console is the web-based user interface for managing your systems.

The console can:

- browse and compare resources on your nodes in real time.
- analyze events and reports to help you visualize your infrastructure over time.
- browse inventory data and backed-up file contents from your nodes.
- group and classify nodes, and control the Puppet classes they receive in their catalogs.
- manage user access, including integration with external user directories.

The console leverages data created and collected by PE to provide insight into your infrastructure.

**RBAC**

In PE, you can use RBAC to manage user permissions. Permissions define what actions users can perform on designated objects.

For example:

- Can the user grant password reset tokens to other users who have forgotten their passwords?
- Can the user edit a local user's role or permissions?
- Can the user edit class parameters in a node group?

The RBAC service can connect to external LDAP directories. This means that you can create and manage users locally in PE, import users and groups from an existing directory, or do a combination of both. PE supports OpenLDAP and Active Directory.

You can interact with the RBAC and activity services through the console. Alternatively, you can use the RBAC service API and the activity service API. The activity service logs events for user roles, users, and user groups.

PE users generate tokens to authenticate their access to certain command line tools and API endpoints. Authentication tokens are used to manage access to the following PE services and tools: Puppet orchestrator, Code Manager, Node Classifier, role-based access control (RBAC), and the activity service.

Authentication tokens are tied to the permissions granted to the user through RBAC, and provide users with the appropriate access to HTTP requests.

**Node classifier**

PE comes with its own node classifier (NC), which is built into the console.
Classification is when you configure your managed nodes by assigning classes to them. Classes provide the Puppet code—distributed in modules—that enable you to define the function of a managed node, or apply specific settings and values to it. For example, you might want all of your managed nodes to have time synchronized across them. In this case, you would group the nodes in the NC, apply an NTP class to the group, and set a parameter on that class to point at a specific NTP server.

You can create your own classes, or you can take advantage of the many classes that have already been created by the Puppet community. Reduce the potential for new bugs and to save yourself some time by using existing classes from modules on the Forge, many of which are approved or supported by Puppet, Inc.

You can also classify nodes using the NC API.

**Related information**

Monitoring infrastructure state on page 249
When nodes fetch their configurations from the Puppet master, they send back inventory data and a report of their run. This information is summarized on the Status page in the console.

Managing access on page 193
Role-based access control, more succinctly called RBAC, is used to grant individual users the permission to perform specific actions. Permissions are grouped into user roles, and each user is assigned at least one user role.

Endpoints on page 214
The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.

Activity service API on page 242
The activity service logs changes to role-based access control (RBAC) entities, such as users, directory groups, and user roles.

Token endpoints on page 228
A user’s access to PE services can be controlled using authentication tokens. Users can generate their own authentication tokens using the token endpoint.

Setting PE RBAC permissions and token authentication for orchestrator on page 434
Before you run any orchestrator jobs, you need to set the appropriate permissions in PE role-based access control (RBAC) and establish token-based authentication.

Request an authentication token for deployments on page 58
Request an authentication token for the deployment user to enable secure deployment of your code.

Authenticating to the node classifier API on page 359
You need to authenticate requests to the node classifier API. You can do this using RBAC authentication tokens or with the RBAC certificate whitelist.

Forming RBAC API requests on page 215
Token-based authentication is required to access the RBAC API. You can authenticate requests by using either user authentication tokens or whitelisted certificates.

Forming activity service API requests on page 242
Token-based authentication is required to access the activity service API. You can authenticate requests with user authentication tokens or whitelisted certificates.

User permissions and user roles on page 194
The "role" in role-based access control refers to a system of user roles, which are assigned to user groups and their users. Those roles contain permissions, which define what a user can or can't do within PE.

Grouping and classifying nodes on page 296
Configure nodes by assigning classes, parameters, and variables to them. This is called classification.

Node classifier API v1 on page 358
These are the endpoints for the node classifier v1 API.

**Code Manager and r10k**

PE includes tools for managing and deploying your Puppet code: Code Manager and r10k. These tools install modules, create and maintain environments, and deploy code to your masters, all based on code you keep in Git. They sync the code to your masters, so that all your servers start running the new code at the same time, without interrupting agent runs.

Both Code Manager and r10k are built into PE, so you don't have to install anything, but you need to have a basic familiarity with Git.

Code Manager comes with a command line tool which you can use to trigger code deployments from the command line.

**Related information**

- [Managing and deploying Puppet code](#) on page 577
  Puppet Enterprise (PE) includes built-in tools for managing and deploying your Puppet infrastructure. Code Manager and r10k are code management tools that automatically install modules, create and maintain environments, and deploy new code to your masters, all based on version control of your Puppet code and data.
- [Triggering Code Manager on the command line](#) on page 601
  The `puppet-code` command allows you to trigger Code Manager from the command line to deploy your environments.
- [Running jobs with Puppet orchestrator](#) on page 429
  With the Puppet orchestrator, you can run three types of "jobs": on-demand Puppet jobs, task runs, and plan runs.

**Orchestration services**

Orchestration services is the underlying toolset that drives Puppet Application Orchestration and the Puppet orchestrator.

Puppet Application Orchestration provides Puppet language extensions and command-line tools to help you configure and manage multi-service and multi-node applications. Specifically, application orchestration is:

- Puppet language elements for describing configuration relationships between components of a distributed application.

  For example, in a three-tier stack application infrastructure—a load-balancer, an application/web server, and a database server—these servers have dependencies on one another. You want the application server to know where the database service is and how they connect, so that you can cleanly bring up the application. You then want the load balancer to automatically configure itself to balance demand on a number of application servers. And if you update the configuration of these machines, or roll out a new application release, you want the three tiers to reconfigure in the correct order.

- A service that orchestrates ordered configuration enforcement from the node level to the environment level.

  The orchestrator is a command-line tool for planning, executing, and inspecting orchestration jobs. For example, you can use it to review application instances declared in an environment, or to enforce change on the environment level without waiting for nodes to check in in regular 30-min intervals.

  The orchestration service interacts with PuppetDB to retrieve facts about nodes. To run orchestrator jobs, users must first authenticate to Puppet Access, which verifies their user and permission profile as managed in RBAC.

**PE databases**

PE uses PostgreSQL as a database backend. You can use an existing instance, or PE can install and manage a new one.

The PE PostgreSQL instance includes the following databases:
<table>
<thead>
<tr>
<th>Database</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-activity</td>
<td>Activity data from the Classifier, including who, what and when</td>
</tr>
<tr>
<td>pe-classifier</td>
<td>Classification data, all node group information</td>
</tr>
<tr>
<td>pe-puppetdb</td>
<td>Exported resources, catalogs, facts, and reports (see more, below)</td>
</tr>
<tr>
<td>pe-rbac</td>
<td>Users, permissions, and AD/LDAP info</td>
</tr>
<tr>
<td>pe-orchestrator</td>
<td>Details about job runs, users, nodes, and run results</td>
</tr>
</tbody>
</table>

**PuppetDB**

PuppetDB collects data generated throughout your Puppet infrastructure. It enables advanced features like exported resources, and is the database from which the various components and services in PE access data. Agent run reports are stored in PuppetDB.

See the PuppetDB overview for more information.

**Related information**

Database maintenance on page 652

You can optimize the Puppet Enterprise (PE) databases to improve performance.

**Security and communications**

The services and components in PE use a variety of communication and security protocols.

<table>
<thead>
<tr>

**Master and agent compatibility**

Use this table to verify that you're using a compatible version of the agent for your PE or Puppet master.

<table>
<thead>
<tr>
<th>Agent</th>
<th>PE 3.x Puppet 3.x</th>
<th>PE 2015.1 through 2017.2 Puppet 4.x</th>
<th>PE 2017.3 through 2018.1 Puppet 5.x</th>
<th>PE 2019.1 and later Puppet 6.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.x</td>
<td>#</td>
<td>#</td>
<td>#</td>
<td>#</td>
</tr>
<tr>
<td>4.x</td>
<td>#</td>
<td>#</td>
<td>#</td>
<td>#</td>
</tr>
</tbody>
</table>
Note:
• Puppet 3.x has reached end of life and is not actively developed or tested. We retain agent 3.x compatibility with later versions of the master only to enable upgrades.
• PE 2019.0 and later uses a new intermediate certificate authority architecture introduced in Puppet Server 6.0. When you update to PE 2019.0 or later, you have several options for whether and when to adopt the new intermediate certificate architecture. For details, see the PE upgrade cautions.

Related information
Upgrade cautions on page 139
These are the major changes to PE since the last long-term support release, 2018.1. Review these recommendations and plan accordingly before upgrading to this version.

Task compatibility
This table shows which version of the Puppet task specification is compatible with each version of PE.

<table>
<thead>
<tr>
<th>PE version</th>
<th>Puppet task specification (GitHub)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019.0.1+</td>
<td>version 1, revision 3</td>
</tr>
<tr>
<td>2019.0.0+</td>
<td>version 1, revision 2</td>
</tr>
<tr>
<td>2017.3.0+</td>
<td>version 1, revision 1</td>
</tr>
</tbody>
</table>

PE and FIPS compliance
Puppet Enterprise (PE) complies with Federal Information Processing Standard (FIPS) 140-2 standards and is fully operable on select FIPS-compliant platforms.

To install FIPS-compliant PE, simply install your master and agents on a supported platform with FIPS mode enabled. Master and compiler nodes must be configured with sufficient available entropy or the installation process fails.

Changes in FIPS-compliant installations
In order to operate on FIPS platforms in compliance mode, PE includes the following changes:
• All components are built and packaged against system OpenSSL for the master, or against OpenSSL built in FIPS mode for agents.
• All use of MD5 hashes for security has been eliminated and replaced.
• Forge and module tooling use SHA-256 hashes to verify the identity of modules.
• Proper random number generation devices are used on all platforms.
• All Java and Clojure components use FIPS Bouncy Castle encryption providers on FIPS platforms.

Limitations and cautions for FIPS-compliant installations
Be aware of the following when installing FIPS-compliant PE.
• Upgrading from non-FIPS-compliant versions of PE to FIPS-compliant PE is not supported.
• Disaster recovery configurations are not supported for FIPS-compliant PE.
• FIPS-compliant installations don't support extensions that use the standard Ruby Open SSL library, such as heiraeyaml.
• Due to a known issue with the pe-client-tools packages, puppet code and puppet db commands fail with SSL handshake errors when run on FIPS-enabled hardware. To use puppet db commands on a FIPS-enabled machine, install the puppetdb_cli Ruby gem. To use puppet code commands on a FIPS-enabled machine, use the Code Manager API.

Related information
Supported operating systems and devices on page 77
When choosing an operating system, first consider the machine's role. Different roles support different operating systems and architectures.

Getting support
You can get commercial support for versions of PE in mainstream and extended support. You can also get support from our user community.

Puppet Enterprise support life cycle
Some of our releases have long term support (LTS); others have short term support (STS). For each release, there are three phases of product support: Mainstream support, Extended support, and End of Life (EOL).

For full information about types of releases, support phases and dates for each release, frequency of releases, and recommendations for upgrading, see the Puppet Enterprise support lifecycle page.

If the latest release with the most up-to-date features is right for you, Download, try, or upgrade Puppet Enterprise. Alternatively, download an older supported release from Previous releases.

Open source tools and libraries
PE uses open source tools and libraries. We use both externally maintained components (such as Ruby, PostgreSQL, and the JVM) and also projects which we own and maintain (such as Facter, Puppet agent, Puppet Server, and PuppetDB.)

Projects which we own and maintain are "upstream" of our commercial releases. Our open source projects move faster and have shorter support life cycles than PE. We might discontinue updates to our open source platform components before their commercial EOL dates. We vet upstream security and feature releases and update supported versions according to customer demand and our Security policy.

Support portal
We provide responsive, dependable, quality support to resolve any issues regarding the installation, operation, and use of Puppet Enterprise (PE).

There are two levels of commercial support plans for PE: Standard and Premium. Both allow you to report your support issues to our confidential customer support portal. When you purchase PE, you receive an account and log-on for the portal, which includes access to our knowledge base.

Note: We use the term "standard installation" to refer to a PE installation of up to 4,000 nodes. A Standard Support Plan is not limited to this installation type, however. Standard here refers to the support level, not the size of the PE installation.

Puppet metrics collector
The Puppet metrics collector can help troubleshoot performance issues with PE components.

Puppet Professional Services and Support use and recommend the tool to help optimize PE installations.
The Puppet metrics collector is available from the Forge at https://forge.puppet.com/puppetlabs/puppet_metrics_collector.

**PE support script**

When seeking support, you might be asked to run an information-gathering support script. This script collects a large amount of system information and PE diagnostics, compresses the data, and prints the location of the zipped tarball when it finishes running.

The script is provided by the `pe_support_script` module bundled with the installer.

**Running the support script**

Run the support script on the command line of your PE master or any agent node running Red Hat Enterprise Linux, Ubuntu, or SUSE Linux Enterprise Server operating systems with the command: `/opt/puppetlabs/bin/puppet enterprise support`.

Use these options when you run the support script to modify the output:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--verbose</td>
<td>Logs verbosely.</td>
</tr>
<tr>
<td>--debug</td>
<td>Logs debug information.</td>
</tr>
<tr>
<td>--classifier</td>
<td>Collects classification data.</td>
</tr>
<tr>
<td>--dir &lt;DIRECTORY&gt;</td>
<td>Specifies where to save the support script's resulting tarball.</td>
</tr>
<tr>
<td>--ticket &lt;NUMBER&gt;</td>
<td>Specifies a support ticket number for record-keeping purposes.</td>
</tr>
<tr>
<td>--encrypt</td>
<td>Encrypts the support script's resulting tarball with GnuPG encryption.</td>
</tr>
</tbody>
</table>

**Note:** You must have GPG or GPG2 available in your PATH in order to encrypt the tarball.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--log-age</td>
<td>Specifies how many days worth of logs the support script collects. Valid values are positive integers or <code>all</code> to collect all logs, up to 1 GB per log.</td>
</tr>
</tbody>
</table>

The next iteration of the support script, version 3, is currently under development and may be selected by running `/opt/puppetlabs/bin/puppet enterprise support --v3`. This new version of the support script has more options, which can be used in addition to the list in the table above.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--v3</td>
<td>Activate version 3 of the support script. This option is required in order to use any other option listed in this table.</td>
</tr>
<tr>
<td>--list</td>
<td>List diagnostics that may be enabled or disabled. Diagnostics labeled &quot;opt-in&quot; must be explicitly enabled. All others are enabled by default.</td>
</tr>
<tr>
<td>--enable &lt;LIST&gt;</td>
<td>A comma-separated list of diagnostic names to enable. Use the --list option to print available names. The --enable option must be used to activate diagnostics marked as &quot;opt-in.&quot;</td>
</tr>
<tr>
<td>--disable &lt;LIST&gt;</td>
<td>A comma-separated list of diagnostic names to enable. Use the --list option to print available names.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>--only &lt;LIST&gt;</td>
<td>A comma-separated list of diagnostic names to enable. All other diagnostics will be disabled. Use the --list option to print available names.</td>
</tr>
<tr>
<td>--upload</td>
<td>Upload the output tarball to Puppet Support via SFTP. Requires the --ticket &lt;NUMBER&gt; option to be used.</td>
</tr>
<tr>
<td>--upload_disable_host_key_check</td>
<td>Disable SFTP host key checking. See Support article KB#0305 for a list of current host key values.</td>
</tr>
<tr>
<td>--upload_user &lt;USER&gt;</td>
<td>Specify a SFTP user to use when uploading. If not specified, a shared write-only account will be used.</td>
</tr>
<tr>
<td>--upload_key &lt;FILE&gt;</td>
<td>Specify a SFTP key to use with --upload_user.</td>
</tr>
</tbody>
</table>

Here are some examples of using the version 3 flags when running the support script:

```bash
# Collect diagnostics for just Puppet and Puppet Server
/opt/puppetlabs/bin/puppet enterprise support --v3 --only puppet,puppetserver

# Enable collection of PE classification
/opt/puppetlabs/bin/puppet enterprise support --v3 --enable pe.console.classifier-groups

# Disable collection of system logs, upload result to Puppet
/opt/puppetlabs/bin/puppet enterprise support --v3 --disable system.logs --upload --ticket 12345
```

Descriptions of diagnostics that can be selected using the --enable, --disable, and --only flags are found in the next section.

**Information collected by the support script**

The following sections describe the information collected by version 1 and version 3 of the support script.

**base-status**

The base-status check collects basic diagnostics about the PE installation. This check is unique in that it is always enabled and is not affected by the --disable or --only flags.

Information collected by the base-status check:

- The version of the support script that is running, the Puppet ticket number, if supplied, and the time at which the script was run.

**system**

The checks in the system scope gather diagnostics, logs, and configuration related to the operating system.

Information collected by the system.config check:

- A copy of /etc/hosts
- A copy of /etc/nsswitch.conf
- A copy of /etc/resolv.conf
- Configuration for the apt, yum, and dnf package managers
- The operating system version
- The umask in effect
- The status of SELinux
- A list of configured network interfaces
- A list of configured firewall rules
- A list of loaded firewall kernel modules

Information collected by the `system.logs` check:

- A copy of the system log (syslog)
- A copy of the kernel log (dmesg)

Information collected by the `system.status` check:

- Values of variables set in the environment
- A list of running processes
- A list of enabled services
- The uptime of the system
- A list of established network connections
- NTP status
- The IP address and hostname of the node running the script, according to DNS
- Disk usage
- RAM usage

**puppet**

The checks in the `puppet` scope gather diagnostics, logs, and configuration related to the Puppet agent services.

Information collected by the `puppet.config` check:

- Facter configuration files:
  - `/etc/puppetlabs/facter/facter.conf`
- Puppet configuration files:
  - `/etc/puppetlabs/puppet/device.conf`
  - `/etc/puppetlabs/puppet/hiera.yaml`
  - `/etc/puppetlabs/puppet/puppet.conf`
- PXP agent configuration files:
  - `/etc/puppetlabs/pxp-agent/modules/`
  - `/etc/puppetlabs/pxp-agent/pxp-agent.conf`

Information collected by the `puppet.logs` check:

- Puppet log files:
  - `/var/log/puppetlabs/puppet`
- JournalD logs for the `puppet` service
- PXP agent log files:
  - `/var/log/puppetlabs/puppet`
- JournalD logs for the `pxp-agent` service

Information collected by the `puppet.status` check:

- `facter -p` output and debug-level messages
- A list of Ruby gems installed for use by Puppet
- Ping output for the Puppet Server the agent is configured to use
- A copy of the following files and directories from the Puppet `statedir`:
  - `classes.txt`
  - `graphs/`
  - `last_run_summary.yaml`
• A listing of metadata (name, size, etc.) of files present in the following directories:
  • /etc/puppetlabs
  • /var/log/puppetlabs
  • /opt/puppetlabs
• A listing of Puppet and PE packages installed on the system along with verification output for each

puppetserver

The checks in the puppetserver scope gather diagnostics, logs, and configuration related to the Puppet Server service.

Information collected by the puppetserver.config check:
• Puppet Server configuration files:
  • /etc/puppetlabs/code/hiera.yaml
  • /etc/puppetlabs/puppet/auth.conf
  • /etc/puppetlabs/puppet/autosign.conf
  • /etc/puppetlabs/puppet/classifier.yaml
  • /etc/puppetlabs/puppet/fileserver.conf
  • /etc/puppetlabs/puppet/hiera.yaml
  • /etc/puppetlabs/puppet/puppet.conf
  • /etc/puppetlabs/puppet/puppetdb.conf
  • /etc/puppetlabs/puppet/routes.yaml
  • /etc/puppetlabs/puppetserver/bootstrap.cfg
  • /etc/puppetlabs/puppetserver/code-manager-request-logging.xml
  • /etc/puppetlabs/puppetserver/conf.d/
  • /etc/puppetlabs/puppetserver/logback.xml
  • /etc/puppetlabs/puppetserver/request-logging.xml
  • /etc/puppetlabs/r10k/r10k.yaml
  • /opt/puppetlabs/server/data/code-manager/r10k.yaml

Information collected by the puppetserver.logs check:
• Puppet Server log files:
  • /var/log/puppetlabs/puppetserver/
  • JournalD logs for the pe-puppetserver service
• r10k log files:
  • /var/log/puppetlabs/r10k/

Information collected by the puppetserver.metrics check:
• Data stored in /opt/puppetlabs/puppet-metrics-collector/puppetserver

Information collected by the puppetserver.status check:
• A list of certificates issued by the Puppet CA
• A list of Ruby gems installed for use by Puppet Server
• Output from the status/v1/services API
• Output from the puppet/v3/environment_modules API
• Output from the puppet/v3/environments API
• environment.conf and hiera.yaml files from each Puppet code environment
• The disk space used by Code Manager cache, storage, client, and staging directories
• The disk space used by the server's File Bucket
• The output of r10k deploy display

puppetdb

© 2020 Puppet, Inc.
The checks in the puppetdb scope gather diagnostics, logs, and configuration related to the PuppetDB service.

Information collected by the puppetdb.config check:
- Configuration files:
  - /etc/puppetlabs/puppetdb/bootstrap.cfg
  - /etc/puppetlabs/puppetdb/certificate-whitelist
  - /etc/puppetlabs/puppetdb/conf.d/
  - /etc/puppetlabs/puppetdb/logback.xml
  - /etc/puppetlabs/puppetdb/request-logging.xml

Information collected by the puppetdb.logs check:
- PuppetDB log files: /var/log/puppetlabs/puppetdb
- JournalD logs for the pe-puppetdb service

Information collected by the puppetdb.metrics check:
- Data stored in /opt/puppetlabs/puppet-metrics-collector/puppetdb

Information collected by the puppetdb.status check:
- Output from the status/v1/services API
- Output from the pdb/admin/v1/summary-stats API
- A list of active certnames from the PQL query nodes[certname] {deactivated is null and expired is null}

pe

The checks in the pe scope gather diagnostics, logs, and configuration related to Puppet Enterprise services.

Information collected by the pe.config check:
- Installer configuration files:
  - /etc/puppetlabs/enterprise/conf.d/
  - /etc/puppetlabs/enterprise/hiera.yaml
  - /etc/puppetlabs/installer/answers.install
- PE client tools configuration files:
  - /etc/puppetlabs/client-tools/orchestrator.conf
  - /etc/puppetlabs/client-tools/puppet-access.conf
  - /etc/puppetlabs/client-tools/puppet-code.conf
  - /etc/puppetlabs/client-tools/puppetdb.conf
  - /etc/puppetlabs/client-tools/services.conf

Information collected by the pe.logs check:
- PE installer log files:
  - /var/log/puppetlabs/installer/
- PE backup and restore log files:
  - /var/log/puppetlabs/pe-backup-tools/
  - /var/log/puppetlabs/puppet_infra_recover_config_cron.log

Information collected by the pe.status check:
- Output from puppet infra status
- Current tuning settings from puppet infra tune
- Recommended tuning settings from puppet infra tune
This check is disabled by default. Information collected by the `pe.file-sync` check when activated by the `--enable` option:

- Puppet manifests and other content from `/etc/puppetlabs/code-staging/
- Puppet manifests and other content stored in Git repos under `/opt/puppetlabs/server/data/puppetserver/filesync`

**pe.console**

The checks in the `pe.console` scope gather diagnostics, logs, and configuration related to the Puppet Enterprise console service.

Information collected by the `pe.console.config` check:

- Configuration files:
  - `/etc/puppetlabs/console-services/bootstrap.cfg`
  - `/etc/puppetlabs/console-services/conf.d/`
  - `/etc/puppetlabs/console-services/logback.xml`
  - `/etc/puppetlabs/console-services/rbac-certificate-whitelist`
  - `/etc/puppetlabs/console-services/request-logging.xml`
  - `/etc/puppetlabs/nginx/conf.d/`
  - `/etc/puppetlabs/nginx/nginx.conf`

Information collected by the `pe.console.logs` check:

- Console log files:
  - `/var/log/puppetlabs/console-services/`
  - `/var/log/puppetlabs/nginx/`
- JournalD logs for the `pe-puppetdb` and `pe-nginx` services

Information collected by the `pe.console.status` check:

- Output from the `/status/v1/services` API
- Directory service connection configuration, with passwords removed

This check is disabled by default. Information collected by the `pe.console.classifier-groups` check when activated by the `--enable` option:

- All classification data provided by the `/v1/groups` API endpoint

**pe.orchestration**

The checks in the `pe.orchestration` scope gather diagnostics, logs, and configuration related to the Puppet Enterprise orchestration services.

Information collected by the `pe.orchestration.config` check:

- ACE server configuration files:
  - `/etc/puppetlabs/puppet/ace-server/conf.d/`
- Bolt server configuration files:
  - `/etc/puppetlabs/puppet/bolt-server/conf.d/`
• Orchestration service configuration files:
  • /etc/puppetlabs/puppet/orchestration-services/bootstrap.cfg
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/analytics.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/auth.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/global.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/inventory.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/metrics.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/orchestrator.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/pcp-broker.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/web-routes.conf
  • /etc/puppetlabs/puppet/orchestration-services/conf.d/webserver.conf
  • /etc/puppetlabs/puppet/orchestration-services/logback.xml
  • /etc/puppetlabs/puppet/orchestration-services/request-logging.xml

Information collected by the `pe.orchestration.logs` check:
  • ACE server log files: /var/log/puppetlabs/ace-server/
  • JournalD logs for the `pe-ace-server` service
  • Bolt server log files: /var/log/puppetlabs/bolt-server/
  • JournalD logs for the `pe-bolt-server` service
  • Orchestrator log files: /var/log/puppetlabs/orchestration-services/
  • JournalD logs for the `pe-orchestration-services` service

Information collected by the `pe.orchestration.metrics` check:
  • Data stored in /opt/puppetlabs/puppet-metrics-collector/orchestrator/

Information collected by the `pe.orchestration.status` check:
  • Output from the `/status/v1/services` API

`pe.postgres`

The checks in the `pe.postgres` scope gather diagnostics, logs, and configuration related to the Puppet Enterprise PostgreSQL database.

Information collected by the `pe.postgres.config` check:
  • Configuration files:
    • /opt/puppetlabs/server/data/postgresql/*/data/postgresql.conf
    • /opt/puppetlabs/server/data/postgresql/*/data/postmaster.opts
    • /opt/puppetlabs/server/data/postgresql/*/data/pg_ident.conf
    • /opt/puppetlabs/server/data/postgresql/*/data/pg_hba.conf

Information collected by the `pe.postgres.logs` check:
  • PostgreSQL log files:
    • /var/log/puppetlabs/postgresql/*/b\n    • /opt/puppetlabs/server/data/postgresql/pg_upgrade_internal.log
    • /opt/puppetlabs/server/data/postgresql/pg_upgrade_server.log
    • /opt/puppetlabs/server/data/postgresql/pg_upgrade_utility.log
  • JournalD logs for the `pe-postgresql` service

Information collected by the `pe.postgres.status` check:
  • A list of setting values that the database is using while running
  • A list of currently established database connections and the queries being executed
  • A distribution of Puppet run start times for thundering herd detection
• The status of any configured replication slots
• The status of any active replication connections
• The size of database directories on disk
• The size of databases as reported by the database service
• The size of tables and indices within databases

Community support
As a Puppet Enterprise customer you are more than welcome to participate in our large and helpful open source community as well as report issues against the open source project.

• Join the Puppet Enterprise user group. Your request to join is sent to Puppet, Inc. for authorization and you receive an email when you’ve been added to the user group.
  • Click on “Sign in and apply for membership.”
  • Click on “Enter your email address to access the document.”
  • Enter your email address.
• Join the open source Puppet user group.
• Join the Puppet developers group.
• Report issues with the open source Puppet project.

Using the PE docs
Review these tips to get the most out of the PE docs.

Archived PE docs
PE docs for recent end-of-life (EOL) or superseded product versions are archived in place, meaning that we continue to host them at their original URLs, but we limit their visibility on the main docs site and no longer update them. You can access archived-in-place docs using their original URLs, or from the links here.

PE docs for EOL versions earlier than those listed here are archived in our PE docs GitHub archive.

Usage notes for example commands

Review these guidelines to help you understand and use example commands throughout PE docs.

Using puppet commands to generate cURL arguments

The examples used throughout the PE docs rely on puppet commands to populate some cURL arguments, taking the guesswork out of providing those values. For example, you might see something like this:

```
url="http://$(puppet config print server):4433"
curl "$url"
```

Puppet commands can return different values depending on various conditions. In order for the cURL examples to work as intended, one or both of these conditions must be true:

- The entire example (including setting the environment variables and calling the curl command) is run as root on the Puppet Server.
- The computer on which you run the commands has both puppet-agent and pe-client-tools packages installed and configured. See the link below for information on installing and configuring pe-client-tools.

To run the command on a machine that doesn’t satisfy either of the above conditions, replace the inline puppet commands with hard-coded values. If you’re unsure about the correct values, run the puppet commands to get reasonable defaults.

Alternative ways to include authentication tokens

Any curl example that contains this line:

```
auth_header="X-Authentication: $(puppet-access show)"
```

can instead use an actual token if you have one available:

```
auth_header="X-Authentication: <TOKEN>"
```

Puppet platform documentation for PE

Puppet Enterprise (PE) is built on the Puppet platform which has several components: Puppet, Puppet Server, Facter, Hiera, and PuppetDB. This page describes each of these platform components, and links to the component docs.

Puppet

- Puppet docs

Puppet is the core of our configuration management platform. It consists of a programming language for describing desired system states, an agent that can enforce desired states, and several other tools and services.

Right now, you’re reading the PE manual; the Puppet reference manual is a separate section of our docs site. After you’ve followed a link there, you can use the navigation sidebar to browse other sections of the manual.

Note: The Puppet manual has information about installing the open source release of Puppet. As a PE user, ignore those pages.

The following pages are good starting points for getting familiar with Puppet:

Language

- An outline of how the Puppet language works.
  - Resources, variables, conditional statements, and relationships and ordering are the fundamental pieces of the Puppet language.
  - Classes and defined types are how you organize Puppet code into useful chunks. Classes are the main unit of Puppet code you’ll be interacting with on a daily basis. You can assign classes to nodes in the PE console.

© 2020 Puppet, Inc.
• **Facts and built-in variables** explains the special variables you can use in your Puppet manifests.

**Modules**

• Most Puppet code goes in modules. We explain how modules work [here](#).
• There are also guides to [installing modules](#) and [publishing modules](#) on the Forge.
• Use the code management features included in PE to control your modules instead of installing by hand. See [Managing and deploying Puppet code](#) (in the PE manual) for more details.

**Services and commands**

• An overview of Puppet’s architecture.
• A list of the main services and commands you’ll interact with.
• Notes on running Puppet’s commands on Windows.

**Built-in resource types and functions**

• The resource type reference has info about all of the built-in Puppet resource types.
• The function reference does the same for the built-in functions.

**Important directories and files**

• Most of your Puppet content goes in environments. Find out more about environments [here](#).
• The `codedir` contains code and data and the `confdir` contains config files. The `modulepath` and the `main manifest` both depend on the current environment.

**Configuration**

• The main config file for Puppet is `/etc/puppetlabs/puppet/puppet.conf`. Learn more about Puppet’s settings, and about `puppet.conf` itself.
• There are also a bunch of other config files used for special purposes. Go to the [page about `puppet.conf`](#) and check the navigation sidebar for a full list.

**Puppet Server**

• [Puppet Server docs](#)

Puppet Server is the JVM application that provides the core Puppet HTTPS services. Whenever Puppet agent checks in to request a configuration catalog for a node, it contacts Puppet Server.

For the most part, PE users don’t need to directly manage Puppet Server, and the Puppet reference manual (above) has all the important info about how Puppet Server evaluates the Puppet language and loads environments and modules. However, some users might need to access the [environment cache](#) and [JRuby pool](#) administrative APIs, and there’s lots of interesting background information in the rest of the Puppet Server docs.

**Note:** The Puppet Server manual has information about installing the open source release of Puppet Server. As a PE user, ignore those pages. Additionally, the Puppet Server config files in PE are managed with a built-in Puppet module; to change most settings, set the appropriate class parameters in the console.

**Facter**

• [Facter docs](#)

Facter is a system profiling tool. Puppet agent uses it to send important system info to Puppet Server, which can access that info when compiling that node’s catalog.

• For a list of variables you can use in your code, check out the [core facts reference](#).
• You can also write your own custom facts. See the [custom fact overview](#) and the [custom fact walkthrough](#).

**Hiera**

• [Hiera docs](#)

Hiera is a hierarchical data lookup tool. You can use it to configure your Puppet classes.
Start with the overview and use the navigation sidebar to get around.

**Note:** Hiera 5 is a backwards-compatible evolution of Hiera, which is built into Puppet. To provide some backwards-compatible features, it uses the classic Hiera 3 codebase. This means “Hiera” is still version 3.x, even though this Puppet Enterprise version uses Hiera 5.

**PuppetDB**

- [PuppetDB docs](#)

PuppetDB collects the data Puppet generates, and offers a powerful query API for analyzing that data. It’s the foundation of the PE console, and you can also use the API to build your own applications.

If you’re interacting with PuppetDB directly, you’ll mostly be using the query API.

- [The query tutorial page](#) walks you through the process of building and executing a query.
- [The query structure page](#) explains the fundamentals of using the query API.
- [The API curl tips page](#) has useful information about testing the API from the command line.
- You can use the navigation sidebar to browse the rest of the query API docs.

**Note:** The PuppetDB manual has information about installing the open source release of PuppetDB. As a PE user, ignore those pages.

**Related information**

- [Managing and deploying Puppet code](#) on page 577

Puppet Enterprise (PE) includes built-in tools for managing and deploying your Puppet infrastructure. Code Manager and r10k are code management tools that automatically install modules, create and maintain environments, and deploy new code to your masters, all based on version control of your Puppet code and data.

**API index**

APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

**Puppet Enterprise APIs**

For information on port requirements, see the System Configuration documents.

**Release notes**

These release notes contain important information about Puppet Enterprise® 2019.8.

This release incorporates new features, enhancements, and resolved issues from all previous major releases. If you're upgrading from an earlier version of PE, check the release notes for any interim versions for details about additional improvements in this release over your current release.

**Note:** This version of documentation represents the latest update in this release stream. There might be differences in features or functionality from previous releases in this stream.

PE uses certain components of open source Puppet. Refer to the component release notes for information about those releases.

• **PE release notes** on page 36
  These are the new features, enhancements, resolved issues, and deprecations in this version of PE.

• **PE known issues** on page 41
  These are the known issues in PE 2019.8.

• **What's new since PE 2018.1** on page 46
  These are the major new features, enhancements, deprecations, and removals since the previous LTS release. Most bug fixes were ported back to PE 2018.1 if they affected that version, so there aren't any notable resolved issues between LTS versions.

---

**PE release notes**

These are the new features, enhancements, resolved issues, and deprecations in this version of PE.

**PE 2019.8.1**

**Enhancements**

**Value reporting**

A new values API reports details about automated changes that PE makes to nodes, and provides an estimate of time freed by each type of change based on intelligent defaults or values you provide. You can also specify an average hourly salary and see an estimate of cost savings for all automated changes.

**Console navigation and workflow improvements**

There are several improvements to the console, including new sections and renamed pages. For example, the Classification page was renamed Node groups. In the console, see the **New in 2019.8** page for a full list of changes.

**Compiler conversion runs in parallel**

When you convert all compilers at one time with `puppet infrastructure run convert_legacy_compiler all=true`, the process is now noticeably faster due to streamlining in when Puppet runs occur on target hosts.

**Console displays enum and boolean plan parameter values in select menu**

You can select plan parameters that are boolean or enum types from a drop down menu in the Value field.

**Updates to metrics endpoints**

Access to endpoints under /metrics are now controlled by trapperkeeper-authorization and configured in the Puppet Server auth.conf file. The default rule allows remote access with a valid Puppet certificate.

Setting the v2 metrics endpoint to debug no longer displays debug messages from Jolokia. In order to see debugging messages, set a configuration value in addition to the usual logback changes.

**Deprecations and removals**

**Application orchestration features in the Puppet language**

Support for application orchestration was dropped in PE version 2019.1 and later. These application orchestration features of the Puppet language are also now deprecated:

- **Keywords:** site, application, consumes, and produces
- **Metaparameters:** export and consume
- **Resource kinds:** application, site, capability_mapping

• Puppet::Parser::Compiler::CatalogValidator::SiteValidator
  Puppet::Parser::Compiler::CatalogValidator::EnvironmentRelationshipValidator
• Puppet::Type#is_capability?
• Puppet::Type#application?
• Environment catalog REST API

Resolved issues

Upgrading Windows agents using the puppet_agent module could restart non-Puppet services

If you're using a log aggregator, upgrading Windows agents using the puppet_agent module could cause non-Puppet services to restart.

Upgrading agents using the puppet_agent module could produce non-breaking errors

Upgrading agents from versions 6.14 or 6.15 using the puppet-agent module could produce errors about an unavailable file resource or unknown HTTP resource. These errors occurred only during the initial Puppet agent run, when the agent was still using versions 6.14 or 6.15 with an updated master. The error resolved after the puppet-agent service restarted.

Pre-upgrade check produced inaccurate errors on standalone PE-PostgreSQL nodes

When you ran the installer on a standalone PE-PostgreSQL node to upgrade it, you saw an error like this:

```
## Pre-Upgrade Checks
Warning: Puppet agent is not running.
Error: No configuration file found at /etc/puppetlabs/client-tools/services.conf. This file is installed automatically on Puppet Server nodes.
Make sure you are running the command on a primary master, primary master replica, or compile master.
Error: Try 'puppet infrastructure help status' for usage
```

The error occurred because the pre-upgrade check verified services running on the master which were not present on standalone PE-PostgreSQL nodes.

Upgrade could fail with custom structured facts

If you use custom facts that use structured facts, upgrade could fail with an error related to your custom fact, for example: undefined method '[]' for nil:NilClass (Puppet::Error).

Upgrade commands failed if PXP agents were configured to connect to load balancers

In installations with load balancers, the puppet infrastructure upgrade commands could fail if the PXP agent on infrastructure nodes connected to load balancers instead of to the master. The upgrade plan now verifies configuration and prompts you to fix any issues before continuing with the upgrade.

Compiler upgrade could fail to upgrade Puppet Server

The puppet infrastructure upgrade compiler command could fail to upgrade Puppet Server depending on how the catalog was built for performing the upgrade.

Converting all legacy compilers failed in disaster recovery installations

With disaster recovery enabled, the command to convert legacy compilers with the option all=true failed.
Converting legacy compilers failed with autosigning enabled

Running `puppet infrastructure run convert_legacy_compiler` with autosigning enabled caused the conversion to fail during certificate regeneration.

Converting legacy compilers could fail with DNS alternative names

If `dns_alt_names` were specified in the `[agent]` section of `puppet.conf`, the `puppet infrastructure run convert_legacy_compiler` command failed because it didn't recognize the alternative names. As a temporary workaround, we recommended moving `dns_alt_names` to the `[main]` section of `puppet.conf` on the compilers to be converted, however `[agent]` is the preferred section to specify this parameter. The compiler conversion command now recognizes DNS alternative in either the `[agent]` or `[main]` section of `puppet.conf`.

Missing package dependencies for SUSE Linux Enterprise Server agent nodes

On agent nodes running SUSE Linux Enterprise Server 15, the `libyaml-cpp` package and operating system packages prefixed with `libboost_` were no longer bundled with Puppet agent, and also might not have been included in the operating system.

Command to regenerate agent certificates didn’t work with nodes behind a load balancer

In large and extra-large installations with load balancers, the command `puppet infrastructure run regenerate_agent_certificate` failed because compilers didn’t have the tasks needed to run the command, and agent nodes don’t communicate directly with the master.

With lockless code deploy enabled, deleted branches could increase disk use

If you deleted a branch from your control repository with lockless deploys enabled, some artifacts could remain on disk and increase your disk use.

With lockless code deploy enabled, deploying with `--wait` could produce an erroneous timeout

Deploying code from the command line or API with the `--wait` flag produced a timeout error, even though the code deploy completed.

The `blackout_windows` parameter in `pe_patch` class couldn’t handle time zones with negative UTC offset

If you used a negative value to offset the timezone when setting the `blackout_windows` parameter for patching node groups, the `pe_patch` fact would return an error.

The `pe_patch` fact wouldn’t generate if there was a parsing error

The `pe_patch` fact couldn't be generated if there was an error when parsing the latest cached catalog for the node. Additionally, if you did not have `puppetlabs-stdlib` installed, packages that were fixed to a particular version in the node’s catalog were not recognized by `pe_patch`.

Node search input didn’t respond to Enter key

The node name search bar on the Nodes page in the console didn’t respond to the Enter key to search for a node and you had to select Submit manually. You can now use Enter to search for nodes.

Console radiator bars had a width of zero

In the console, the colored bars in the radiator were broken and didn't show the correct layout. The radiator has been fixed.
New features

Patch management
You can now manage patches on *nix and Windows nodes in the Patch Management section of the console. After setting up patching node groups, you can view the patch status for your nodes, filter available patches by type and operating system, and run a pre-filled task to apply patches to selected nodes from the Patches page. For information on configuring patch management and applying patches, see Managing patches on page 421.

Lockless code deploys
Using Code Manager, you can now optionally deploy code to versioned code directories rather than the live code directory. This change enables Puppet Server to continue serving catalog requests even as you deploy code.

You can enable lockless code deploys by setting puppet Enterprise::profile::master::versioned_deploys to true. For more information about lockless code deploys, see Deploy code without blocking requests to Puppet Server on page 592.

Note: Lockless deploys are an experimental feature which might experience breaking changes in future releases. We recommend testing lockless deploys in a non-production environment before enabling it in production.

Enhancements

Improvements to puppet infrastructure upgrade commands
When you specify more than one compiler to upgrade, the puppet infrastructure upgrade compiler command now upgrades all compilers at the same time, rather than sequentially. Additionally, with both the compiler and replica upgrade commands, you can now specify the location of an authentication token other than the default. For example: puppet infrastructure upgrade compiler --token-file=<PATH_TO_TOKEN>.

More secure code deploys
Permissions for the Puppet code directory are now managed by file sync directly, instead of relying on symlinks. This change improves security during code deployment.

Logging for puppet infrastructure commands that use the orchestrator
A new log file located at /var/log/puppetlabs/installer/orchestrator_info.log contains run details about puppet infrastructure commands that use the orchestrator, including the commands to provision and upgrade compilers, convert legacy compilers, and regenerate agent and compiler certificates.

Improved error handling for plans
Before running plans, the built-in check for node connectivity now provides more descriptive error messages, such as host key verification failures.

Unspecified default values for tasks and plans are supplied automatically
When you run tasks or plans through the orchestrator API or the console, default values are supplied to the job when the user does not supply them. Parameters that have a default value are treated as optional in the console.

Note: The parameters you supply the first time you run a task will be used for subsequent task runs when using the Run again feature on the Task details page.

New scheduling options in the console
You can now specify scheduled tasks and Puppet jobs to run every two weeks or every four weeks.
Plan support for apply() on pcp transports

Plans now support using the apply_prep() function and blocks of Puppet code within calls to apply(). The feature is only available on targets connected to PE using the PCP transport and does not work on nodes connected over SSH or WinRM.

Support for new options in the command/deploy endpoint

The following options were added to the orchestrator's POST /command/deploy on page 455 endpoint:

- filetimeout
- http_connect_timeout
- http_keepalive_timeout
- http_read_timeout
- ordering
- skip_tags
- tags
- use_cached_catalog
- usecacheonfailure

Platform support

This version adds support for these platforms

Agent

- macOS 10.15

Deprecations and removals

Razor removed

Razor has been removed from PE in this release. If you want to continue using Razor, you can use the open source version of the tool.

Support for bolt.yaml settings in plans removed

Settings from bolt.yaml are no longer read from the environment directory. The modulepath setting is only configurable from environment.conf.

Platforms removed

Support for these platforms is removed in this release:

Master

- Enterprise Linux 6
- Ubuntu 16.04

Resolved issues

Upgrade removed custom classification rules from PE Master node group

Custom rules that you used to classify compilers in the PE Master node group were removed upon upgrade, or when you ran puppet infrastructure configure.

Upgrade failed with a Could not retrieve facts error

If an invalid custom fact installed on the master couldn't be resolved during upgrade, the upgrade failed with an error similar to this:
Could not retrieve facts ... undefined method `split' for nil:NilClass
(Puppet::Error) from /opt/puppetlabs/installer/lib/ruby/gems/2.5.0/gems/facter-4.0.20/lib/custom_facts/util/loader.rb:125:in `load'

**Upgrading a replica could temporarily lock the agent on the master**

If you tried to run Puppet on your master before the puppet infrastructure upgrade replica command completed, you could encounter an error that a Puppet run was already in progress.

**FIPS installs didn't fully support cert chain validation**

In FIPS environments, RBAC could not connect to LDAP using a pem or jks file.

**Command to remove old PostgreSQL versions failed on Ubuntu**

When run on Ubuntu nodes, the puppet infrastructure run remove_old_postgresql_versions command failed, erroneously reporting that PostgreSQL wasn't installed.

**Enabling a replica could fail immediately after provisioning**

When running puppet infrastructure provision replica --enable, the command could fail after the replica was provisioned but before it was enabled if services on the replica were still starting up. The command now waits for services to start and verifies that replication has completed before enabling the replica.

**Ubuntu 20.04 couldn't be installed with PE package management**

Ubuntu 20.04 wasn't available for installation as a pe_repo class, even though it was a supported agent platform.

**Loading plan lists crashed console services**

When plan run results were large, the console crashed due to high memory usage on the Plan details page. An optional results query parameter has been added to the GET/plan_jobs endpoint. This parameter keeps you from experiencing high memory usage in the console when loading results for large plan runs.

**Default value for tasks and plans dropped in middleware**

When a task had a default value of false or null, the console metadata panel did not display the default value.

**Event inspector displayed wrong table types**

Browsing the event inspector sometimes created inconsistencies in tables and errors in table links.

---

**PE known issues**

These are the known issues in PE 2019.8.

**Installation and upgrade known issues**

These are the known issues for installation and upgrade in this release.

**Upgrade fails with an unenabled replica**

PE upgrade fails if you have a provisioned, but not enabled, replica. As a workaround, edit the PE Master node group configuration with these parameters for the puppet_enterprise::profile::master class:

- puppetdb_port = [8081]
- puppetdb_host = ["MASTERS_FQDN_EXAMPLE"]
Compiler provisioning fails if a single compiler is unresponsive

The puppet infrastructure provision compiler command fails if any compiler in your pool fails a pre-provisioning health check.

Automated Puppet runs can fail after running compiler commands

After provisioning or converting compilers with puppet infrastructure commands, automated Puppet runs can fail because the Puppet service hasn’t restarted. As a workaround, manually restart the Puppet service after running the command.

```
puppet resource service puppet ensure=stopped
puppet resource service puppet ensure=running
```

Upgrades can fail when using custom database certificate parameters

When upgrading an infrastructure with an unmanaged PostgreSQL database to this version of PE, the upgrade can fail and result in downtime if the databases use custom certificates not issued by the PE certificate authority. This is the case even if you configured the database_properties parameters in pe.conf to set a custom sslrootcert. The upgrader ignores these custom certificate settings.

To manually override the upgrader's certificate settings, run these commands, replacing <NEW CERT> with the name of your custom certificate.

```
  rpm -iUv /opt/puppetlabs/server/data/packages/public/2019.3.0/el-7-x86_64-6.12.0/pe-modules-2019.3.0.2-1.el7.x86_64.rpm
  sed -i 's#/etc/puppetlabs/puppet/ssl/certs/ca.pem#/etc/puppetlabs/puppet/ssl/<NEW CERT>.pem#'
  /opt/puppetlabs/server/data/environments/enterprise/modules/pe_manager/lib/puppet_x/puppetlabs/meep/configure/postgres.rb
  ./puppet-enterprise-installer --force
```

**Note:** The first step in the code block above includes paths specific to the PE version you're upgrading to. Replace these version information as needed.

Converting legacy compilers fails with an external certificate authority

If you use an external certificate authority (CA), the puppet infrastructure run convert_legacy_compiler command fails with an error during the certificate-signing step.

```
Agent_cert_regen: ERROR: Failed to regenerate agent certificate on node <compiler-node.domain.com>
Agent_cert_regen: bolt/run-failure:Plan aborted: run_task 'enterprise_tasks::sign' failed on 1 target
Agent_cert_regen: puppetlabs.sign/sign-cert-failed Could not sign request for host with certname <compiler-node.domain.com> using caserver <master-host.domain.com>
```

To work around this issue when it appears:

1. Log on to the CA server and manually sign certificates for the compiler.
2. On the compiler, run Puppet: puppet agent -t
3. Unpin the compiler from PE Master group, either from the console, or from the CLI using the command: /opt/puppetlabs/bin/puppet resource pe_node_group "PE Master" unpinned="<COMPILER_FQDN>"
4. On your master, in the pe.conf file, remove the entry
```
puppet_enterprise::profile::database::private_temp_puppetdb_host
```
5. If you have an external PE-PostgreSQL node, run Puppet on that node: puppet agent -t
6. Run Puppet on your master: puppet agent -t

© 2020 Puppet, Inc.
7. Run Puppet on all compilers: `puppet agent -t`

**Disaster recovery known issues**

These are the known issues for disaster recovery in this release.

**Upgrade fails with an unenabled replica**

PE upgrade fails if you have a provisioned, but not enabled, replica. As a workaround, edit the PE Master node group configuration with these parameters for the `puppet_enterprise::profile::master` class:

- `puppetdb_port = [8081]`
- `puppetdb_host = ["MASTERS_FQDN_EXAMPLE"]`

**Puppet runs can take longer than expected in failover scenarios**

In disaster recovery environments with a provisioned replica, if the master is unreachable, a Puppet run using data from the replica can take up to three times as long as expected (for example, 6 minutes versus 2 minutes).

**FIPS known issues**

These are the known issues with supported platforms in this release.

**Puppet Server FIPS installations don’t support Ruby’s OpenSSL module**

FIPS-compliant installations don’t support extensions that use the standard Ruby Open SSL library, such as heireyaml.

**Errors when using puppet code and puppet db commands on FIPS-enabled hardware**

When the `pe-client-tools` packages are run on FIPS-enabled hardware, `puppet code` and `puppet db` commands fail with SSL handshake errors. To use `puppet db` commands on a FIPS-enabled machine, install the `puppetdb_cli` Ruby gem with the following command:

```
/opt/puppetlabs/puppet/bin/gem install puppetdb_cli --bindir /opt/puppetlabs/bin/
```

To use `puppet code` commands on a FIPS-enabled machine, use the Code Manager API. Alternatively, you can use `pe-client-tools` on a non-FIPS-enabled machine to access a FIPS-enabled master.

**Configuration and maintenance known issues**

These are the known issues for configuration and maintenance in this release.

**Console is inaccessible with PE set to IPv6**

If you specify IPv6, PE Java services still listens to the IPv4 localhost. This mismatch can prevent access to the console as Nginx proxies traffic to the wrong localhost.

As a workaround, set the `java.net.preferIPv6Addresses` property to `true` for console services and PuppetDB:

```
"puppet_enterprise::profile::console::java_args": {
  "Xms": "256m"
  "Xmx": "256m"
  "Djava.net.preferIPv6Addresses": "=true"
}

"puppet_enterprise::profile::puppetdb::java_args": {
  "Xms": "256m"
  "Xmx": "256m"
  "Djava.net.preferIPv6Addresses": "=true"
```

© 2020 Puppet, Inc.
puppet infrastructure recover_configuration misreports success if specified environment doesn't exist

If you specify an invalid environment when running puppet infrastructure recover_configuration, the system erroneously reports that the environment's configuration was saved.

puppet-backup fails if gems are missing from the master's agent environment

The puppet-backup create command might fail if any gem installed on the Puppet Server isn't present on the agent environment on the master. If the gem is either absent or of a different version on the master's agent environment, you get the error "command puppet infrastructure recover_configuration failed".

To fix this, install missing or incorrectly versioned gems on the master's agent environment. To find which gems are causing the error, check the backup logs for gem incompatibility issues with the error message. PE creates backup logs as a report.txt whenever you run a puppet-backup command.

To see what gems and their versions you have installed on your Puppet Server, run the command puppetserver gem list. To see what gems are installed in the agent environment on your master, run /opt/puppetlabs/puppet/bin/gem list.

Orchestration services known issues

These are the known issues for the orchestration services in this release.

The function puppet plan show displays invalid plans when Code Manager is disabled

If Code Manager is disabled, the puppet plan show function and the console will still list plans that are contained in a control repo, but those plans cannot be run. Enable Code Manager to run plans.

Running plans during code deployment can result in failures

If a plan is running during a code deployment, things like compiling apply block statements or downloading and running tasks that are part of a plan might fail. This is because plans run on a combination of PE services, like orchestrator and puppetserver, and the code each service is acting on might get temporarily out of sync during a code deployment.

Master reporting HTTP error after Qualys scan

When running a Qualys scan, the master reports the error "HTTP Security Header Not Detected. Issue at Port 443".

Code management known issues

These are the known issues for Code Manager, r10k, and file sync in this release.

Default SSH URL with TFS fails with Rugged error

Using the default SSH URL with Microsoft Team Foundation Server (TFS) with the rugged provider causes an error of "unable to determine current branches for Git source." This is because the rugged provider expects an @ symbol in the URL format.

To work around this error, replace ssh:// in the default URL with git@

For example, change:

ssh://tfs.puppet.com:22/tfs/DefaultCollection/Puppet/_git/control-repo
GitHub security updates might cause errors with **shellgit**

GitHub has disabled TLSv1, TLSv1.1 and some SSH cipher suites, which can cause automation using older crypto libraries to start failing. If you are using Code Manager or r10k with the `shellgit` provider enabled, you might see negotiation errors on some platforms when fetching modules from the Forge. To resolve these errors, switch your configuration to use the `rugged` provider, or fix `shellgit` by updating your OS package.

**Timeouts when using `--wait` with large deployments or geographically dispersed compilers**

Because the `--wait` flag deploys code to all compilers before returning results, some deployments with a large node count or compilers spread across a large geographic area might experience a timeout. Work around this issue by adjusting the `timeouts_sync` parameter.

**r10k with the Rugged provider can develop a bloated cache**

If you use the `rugged` provider for r10k, repository pruning is not supported. As a result, if you use many short-lived branches, over time the local r10k cache can become bloated and take up significant disk space.

If you encounter this issue, run `git-gc` periodically on any cached repo that is using a large amount of disk space in the cachedir. Alternately, use the `shellgit` provider, which automatically garbage collects the repos according to the normal Git CLI rules.

**Code Manager and r10k do not identify the default branch for module repositories**

When you use Code Manager or r10k to deploy modules from a Git source, the default branch of the source repository is always assumed to be master. If the module repository uses a default branch that is *not* master, an error occurs. To work around this issue, specify the default branch with the `ref:` key in your Puppetfile.

**After an error during the initial run of file sync, Puppet Server won't start**

The first time you run Code Manager and file sync on a master, an error can occur that prevents Puppet Server from starting. To work around this issue:

1. Stop the `pe-puppetserver` service.
2. Locate the `data-dir` variable in `/etc/puppetlabs/puppetserver/conf.d/file-sync.conf`.
3. Remove the directory.
4. Start the `pe-puppetserver` service.

Repeat these steps on each master exhibiting the same symptoms, including any compilers.

**Puppet Server crashes if file sync can't write to the live code directory**

If the live code directory contains content that file sync didn’t expect to find there (for example, someone has made changes directly to the live code directory), Puppet Server crashes.

The following error appears in `puppetserver.log`:

```
org.eclipse.jgit.api.errors.JGitInternalException: Could not delete file /etc/puppetlabs/code/environments/development
at org.eclipse.jgit.api.errors.JGitInternalException: Could not delete file /etc/puppetlabs/code/environments/development
    at org.eclipse.jgit.api.CleanCommand.call(CleanCommand.java:138)
~/[puppet-server-release.jar:na]
```

To recover from this error:
1. Delete the environments in code dir: `find /etc/puppetlabs/code -mindepth 1 -delete`
2. Start the `pe-puppetserver service` using `puppet resource service pe-puppetserver ensure=running`
3. Trigger a Code Manager run by your usual method.

### SSL and certificate known issues

These are the known issues for SSL and certificates in this release.

**Automated Puppet runs can fail after running certificate regeneration commands**

After regenerating certificates with `puppet infrastructure` commands, automated Puppet runs can fail because the Puppet service hasn't restarted. As a workaround, manually restart the Puppet service after running the commands.

```bash
puppet resource service puppet ensure=stopped
puppet resource service puppet ensure=running
```

### What's new since PE 2018.1

These are the major new features, enhancements, deprecations, and removals since the previous LTS release. Most bug fixes were ported back to PE 2018.1 if they affected that version, so there aren't any notable resolved issues between LTS versions.

This list is not intended to be exhaustive, nor to be specific about which interim release a feature or change applied to. For a breakdown of interim releases, see the applicable release notes.

|---------------|--------|--------|--------|---------------|

**Important:** For details about features and fixes that might affect your upgrade, see Upgrade cautions on page 139.

Get familiar with the latest hardware requirements, supported operating systems and browsers, and network configuration details in System requirements on page 73.

**New features**

- **Simplified installation**
  A simplified PE installation process now relies entirely on defaults, apart from specifying a console administrator password. After installation, you can scale or configure your environment as needed.
  You can still install PE using a customized `pe.conf` file by running `./puppet-enterprise-installer -c /tmp/pe.conf`.

- **FIPS compliance**
  PE is now fully operable on select FIPS platforms.

- **Agent installation from the console**
  You can now add *nix and Windows agents to target nodes from the console using `pe_bootstrap` tasks.

- **Support for agentless nodes and network devices**
  You can now add nodes to your inventory without installing the Puppet agent. When you add nodes and their credentials to the inventory, the information is securely stored and made available in the console through remote connections. Authorized users can then run tasks on these nodes without re-entering credentials.

  You can also add network devices to inventory. This feature requires that you have installed modules for device transports in your production environment. By adding connections to those devices to your inventory, you can manage switches and firewalls, and run Puppet and tasks on them, just like other agentless nodes in your infrastructure.
• Plans in PE

You can now run plans in PE from the console, on the command line, or using the orchestrator API /command/plan_run endpoint. A plan is a bundle of tasks that can be combined with other logic to do complex operations, like run multiple tasks with one command or run certain tasks based on the output of another task. You can also write plans with more refined access control, like allowing users access to run a plan containing a specific task under certain circumstances, but not giving them full access to run the task arbitrarily. Plans can be written in Puppet language or YAML and must be installed using Code Manager.

The orchestrator uses more memory to support running plans. If your memory usage is near capacity, allocate additional memory before upgrading. See Configuring Java arguments on page 169 for information about configuring Java services.

• Patch management

You can now manage patches on *nix and Windows nodes from the console. After setting up patching node groups, you can view the patch status for your nodes, filter available patches by type and operating system, and run a prefilled task to apply patches to selected nodes.

• PuppetDB on compilers

To improve scalability in large and extra-large installations, Puppet Server and PuppetDB services are now installed by default on new compilers. This change reduces bottlenecks and enables easier scaling, because your PuppetDB capacity is always matched to your server capacity. New compilers installed with the puppet infrastructure provision compiler command are configured with the PuppetDB service. After upgrading to this or later versions, you can convert existing compilers with the puppet infrastructure run convert_legacy_compiler command.

• Lockless code deploys

Using Code Manager, you can now optionally deploy code to versioned code directories rather than the live code directory. This change enables Puppet Server to continue serving catalog requests even as you deploy code. You can enable lockless code deploys by setting puppet_enterprise::profile::master::versioned_deploys to true.

Note: Lockless deploys are an experimental feature which might experience breaking changes in future releases. We recommend testing the feature in a non-production environment before enabling it in production.

Installation and upgrade enhancements

• PostgreSQL has been upgraded to version 11. For details about upgrading to this version, see PostgreSQL 11 upgrade in PE 2019.2 on page 141.

• Java has been upgraded to version 11. If you customized PE Java services, or use plug-ins that include Java code, test this version thoroughly in a non-production environment before upgrading.

• The puppet infrastructure upgrade compiler and puppet infrastructure upgrade replica commands let you upgrade compilers or your replica from your master. You can specify whether to upgrade one, some, or all of your compilers, and upgrade of multiple compilers occurs at the same time, rather than sequentially.

• The PuppetDB subcommand, delete-reports, speeds upgrade by stopping PuppetDB and deleting all reports and their resource events. You can also now use the console to set resource-events-ttl, which determines how long PuppetDB stores a report's resource events.

• For Windows agents, the agent install script automatically downloads a tarball of plug-ins from the master before the agent runs for the first time. Depending on how many modules you have installed, bulk plug-in sync can speed agent installation significantly.

puppet infrastructure enhancements

• Most puppet infrastructure run commands no longer require configuring SSH as a prerequisite. The commands that affect PuppetDB, including migrate_split_to_mono and enable_ha_failover, use the master's PuppetDB certificate for authentication. The commands for PostgreSQL cleanup after upgrade; legacy compiler conversion; and compiler, replica, and agent certificate regeneration now use the orchestrator. A
new log file located at /var/log/puppetlabs/installer/orchestrator_info.log contains run
details about these commands.

Note: In cases where you're regenerating certificates after recreating your certificate authority, you must still
specify SSH connection details, because nodes can't connect to the orchestrator without a valid certificate.

• Certificates for Windows agents can now be regenerated with a single command, puppet infrastructure
run regenerate_agent_certificate.
• When regenerating agent or master certificates, you can now pass an optional dns_alt_names parameter.
• The puppet infrastructure run regenerate_agent_certificate command includes a
clean_crl parameter. Setting clean_crl to true cleans up the local CRL bundle. When you regenerate
certificates for *nix agents after recreating your certificate authority, you must include this parameter with the
value set to true. If you're regenerating agent certificates without recreating the CA, you don't need to clean up
the CRL.
• Setting up control repositories for Code Manager no longer requires manually creating an SSH directory and
configuring permissions on the key pair and directory. These steps have been automated with the puppet
infrastructure configure command.
• The puppet infrastructure status command now reports status for PostgreSQL as well as the Bolt
and Agentless Catalog Executor (ACE) services.

Disaster recovery enhancements

• We've changed the way we refer to failover capabilities within PE, from high availability to disaster recovery.
This change more accurately reflects the role of a replica in PE installations, and aligns our terminology with
industry standards.
• A replica can now be provisioned up to 3,600 percent faster due to a more efficient method for syncing PuppetDB.
Additionally, you can now enable a replica at the same time that you provision by using the --enable flag with
puppet infrastructure provision replica.
• In disaster recovery installations, the server_list setting now takes precedence over the server setting,
preventing unexpected behavior if you promote a replica.

Task, plan, and Puppet run enhancements

• When you run tasks or plans through the orchestrator API or the console, default values are supplied to the job
when the user does not supply them. Parameters that have a default value are treated as optional in the console.
• Use the SSH or WinRM protocols to run tasks on target nodes that don't have an agent installed.
• Use the new task targets API to fine-tune task permissions automatically.
• plan:run and plan:run:* (all plans) allows more control over permissions in plans.
• Schedule a job to run a recurring task in the console or with the /command/scheduled_task endpoint.
• View and delete scheduled jobs with the /scheduled_jobs endpoint.
• View plan details and information about plan jobs you have run using the /plan_jobs endpoint.
• Exclude the plan results from the GET /plan_jobs endpoint with the results parameter.
• Write a single task that has a Python or Bash implementation for Linux and a PowerShell implementation for
Windows.
• The following options were added to the orchestrator POST /command/deploy endpoint:
  • filetimeout
  • http_connect_timeout
  • http_keepalive_timeout
  • http_read_timeout
  • ordering
  • skip_tags
  • tags
  • use_cached_catalog
  • usecacheonfailure
• The orchestrator now contains a new JRuby pool to facilitate plans in PE. New configuration options are now available as orchestrator settings to provide control over the JRuby pool.
• There is a new endpoint in the orchestrator that retrieves an individual event, with no truncation of the `out_message`. See `GET /plan_jobs/:job-id/event/:event-id` for more information.

Console and console services enhancements

• Navigation and page changes:
  • The `Inspect` section is now `Enforcement`.
  • The `Run` section is now `Orchestration`.
  • The `Overview` page is now `Status`.
  • Puppet runs no longer have a dedicated landing page in the sidebar. Instead, select `Run puppet` on the `Status`, `Reports`, and `Jobs` pages. The `Jobs` page is now reserved exclusively for Puppet run results.
  • The `Task` and `Plan` pages route to their own details page for status information about scheduled, running, or previously run tasks and plans. This change allows you to run a task or plan and view status information about a task or plan run without leaving that section of the console.
  • The `Inventory` page has a new look. Instead of using widgets to install agents, nodes, and devices, each installation type has a button that links to its own page. There are also more help icons and definitions on the page.
  • The `Run` button is now on the `Overview`, `Events`, and `Packages` pages and you can use it to run either a task or Puppet on nodes.
  • Pages in the console now have breadcrumbs, showing you where you are in the interface. The breadcrumbs are links you can use to move to parent pages.
• New task, plan, and Puppet run options and features
  • Run Puppet or a task on a single node from the node details page.
  • Add your own custom PQL queries to the console to run tasks and Puppet on nodes that meet specific conditions. See `Add custom PQL queries to the console` on page 161.
  • In addition to `no-op`, you can now specify `debug`, `trace`, and `eval-trace` run options when running Puppet.
  • You can now specify scheduled tasks and Puppet jobs to run every two weeks or every four weeks.
  • When you run a task or a plan in the console, you can now specify an environment other than `production`.
  • Test connections for nodes and devices before adding them to your inventory. This option is enabled by default on the `Inventory` page. If a connection fails, you can edit the node or device information and try again.
  • Track node usage and see details about the total number of active nodes in your deployment on the `License` page.

Classifier enhancements

• Using an updated classification endpoint for the v2 node classifier API, you can now generate an array of the groups that a node was classified into and sort the list by group name and ID. A new top-scope variable is also available, `$pe_node_groups`.

Code management enhancements

• Setting up control repositories for Code Manager no longer requires manually creating an SSH directory and configuring permissions on the key pair and directory. These steps have been automated with the `puppet infrastructure configure` command.
• Two new keys in the Code Manager `/deploys` endpoint provide greater flexibility in deploying modules.
  • "deploy-modules" indicates whether Code Manager deploys modules from the selected environments.
  • "modules" enables you to list specific modules to deploy within the selected environments.
Platform enhancements

- Puppet Server now uses an intermediate certificate authority architecture by default. When you update to a PE version with this capability, you have several options for whether and when to adopt the new intermediate certificate architecture. For details, see Certificate architecture and handling in PE 2019.0 on page 141.
- The puppetserver ca command replaces the puppet cert command, providing a simplified command line interface that uses the new default intermediate CA architecture. Additionally, the new puppet ssl command helps manage certificates on Puppet agents.
- Puppet Server can now run in multithreaded mode, which allows multiple requests to be processed in parallel by a single JRuby. This mode reduces the memory and CPU requirements of the server when enabled.
- Upgrades to PE 2019.1, 2019.3, and 2019.7 involve database migrations that can slow upgrade significantly. Deleting PuppetDB reports and truncating the resource events table before you upgrade can reduce migration time and lessen your downtime. For details, see PuppetDB migrations in PE 2019.1, 2019.3, and 2019.7 on page 140.
- The puppet node purge command now removes all data for the node from PuppetDB. Previously, the command deactivated the node but didn't delete it, so the node could still appear in PuppetDB queries.

Terminology changes

- We've unified infrastructure terminology across all installation types. We now call compile masters compilers to reflect their role: compiling catalogs. Similarly, we call the master a master, whether or not your installation includes compilers. In high availability installations, the node that replicates data from the master is simply a replica. R.I.P. MoM, master of masters, and primary master replica.
- We've updated the terms we use to talk about PE reference architecture types, and are no longer using the term "monolithic."

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Nodes</th>
<th>Former name</th>
<th>New name</th>
</tr>
</thead>
<tbody>
<tr>
<td>All infrastructure components on the master.</td>
<td>Up to 4,000</td>
<td>Monolithic</td>
<td>Standard</td>
</tr>
<tr>
<td>All infrastructure components on the master, plus one or more compilers and a load balancer.</td>
<td>4,000 to 20,000</td>
<td>Monolithic with compilers</td>
<td>Large</td>
</tr>
<tr>
<td>All infrastructure components on the master, plus one or more compilers and a load balancer, plus a separate node which hosts the PE-PostgreSQL instance.</td>
<td>More than 20,000</td>
<td>Monolithic with compilers and standalone PE-PostgreSQL</td>
<td>Extra large</td>
</tr>
</tbody>
</table>

- We've changed the way we refer to failover capabilities within PE, from high availability to disaster recovery. This change more accurately reflects the role of a replica in PE installations, and aligns our terminology with industry standards.

Changes to default settings

- TLSv1 and TLSv1.1 is now disabled by default to comply with security regulations. You must enable TLSv1 to install agents on AIX, CentOS 5, RHEL 5, SLES 11, Solaris 10, and Windows Server 2008 R2.
- The default setting for strict_hostname_checking in PE was changed to true to resolve a security issue. You must specify the fully qualified domain name of the host when referring to nodes; partial hostname matches, for example node 'foo' are no longer supported.

© 2020 Puppet, Inc.
• Authentication tokens now have a default lifetime of one hour, instead of the previous lifetime of five minutes. This increase accommodates longer-running puppet infrastructure run commands that use authentication tokens.

• The Puppet CA is now configured to allow signing certificates with authorization extensions by default. This change enables easier setup of new compilers. Signing certificates that have authorization extensions is still disabled in the console, however the puppetserver ca CLI displays authorization extensions in its list output, providing all relevant details about certificates you're signing.

• The shared_buffers setting uses less RAM by default due to improvements in calculating PostgreSQL settings.

Deprecations and removals

• MCollective and ActiveMQ have been removed. If you're upgrading from a 2018.1 installation with MCollective enabled, you must take additional steps to ensure a successful upgrade. For details, see MCollective removal in PE 2019.0 on page 142.

• Split and large environment installations, where the master, console, and PuppetDB were installed on separate nodes, are no longer supported, and you can't upgrade to this version with a split install. For instructions on migrating to a standard installation, see Migrate from a split to a standard installation on page 144.

• Legacy compilers without the PuppetDB service are deprecated. You can convert legacy compilers after upgrading.

• Razor has been removed.

• The node graph in the console has been removed. To generate a node graph, use the Puppet VS Code extension.

• bolt.yaml settings are no longer supported in plans. The modulepath setting is only configurable from environment.conf.

• Many types were moved out of the Puppet codebase, and into modules on the Forge. This change enables easier compositability and reusability of the Puppet codebase and enables development to proceed more quickly without risk of destabilizing the rest of Puppet. See the Resource Type Reference page for the full list and links to the Forge modules for those types that moved.

• Java arguments on all Trapperkeeper services are now fully managed by the puppet_enterprise module, and use of pe_ini_subsettings to manage Java arguments is no longer supported. If you add Java arguments to the java_args environment variable using pe_ini_subsettings, the arguments are removed during the next Puppet run.

• The pe_accounts module has been removed. The module was used internally to manage PE users but was superseded several versions ago by the puppetlabs/accounts module. If you're using the pe_accounts module for account management, migrate to the puppetlabs/accounts module.

• These deprecated parameters have been removed:
  • mcollective Middleware_hosts
  • mcollective
  • mcollective Middleware_port
  • mcollective Middleware_user
  • mcollective Middleware_password
  • activity_database_user
  • classifier_database_user
  • orchestrator_database_user
  • rbac_database_user
  • dashboard_port
  • dashboard_database_name
  • dashboard_database_user
  • dashboard_database_password
Getting started with Puppet Enterprise

Puppet Enterprise (PE) is automation software that helps you and your organization be productive and agile while managing your IT infrastructure.

PE is a commercial version of Puppet, our original open source product used by individuals managing smaller infrastructures. It has all the power and control of Puppet, plus a graphical user interface, orchestration services, role-based access control, reporting, and the capacity to manage thousands of nodes. PE incorporates other Puppet-related tools and products to deliver comprehensive configuration management capabilities.

There are two things you need to get started with PE: your content and the Puppet platform.

Content
You develop and store your automation content in a Git repository and upload it onto the Puppet platform. It consists of Puppet code, plan and task code, and Hiera data. You store content in a control repo, which contains bundles of code called modules and references to additional content from external sources, like the Puppet Forge — a repository of thousands of modules made by Puppet developers and the Puppet community.

Puppet platform
The Puppet platform includes the master, compilers, and agents. Use it to assign your desired state to managed systems, orchestrate ad-hoc automation tasks on managed and unmanaged systems, and get reports about configuration automation activity.

In this guide, you will learn how to install PE, add nodes to the console, set up your control repo, and run through an example task of managing webserver configurations — using either Apache to manage a *nix machine or IIS to manage a Windows machine.

Before you begin, check out our video for more information about how Puppet works.

- **Install PE** on page 52
  Installing PE sets up a standard installation, which you can use to try out PE with up to 10 nodes or to manage up to 4,000 nodes.
- **Add nodes to the inventory** on page 54
  Your inventory is the list of nodes managed by Puppet. Add nodes with agents, agentless nodes that connect over SSH or WinRM, or add network devices like network switches and firewalls. Agent nodes help keep your infrastructure in your desired state. Agentless nodes do not have an agent installed, but can do things like run tasks and plans.
- **Add code and set up Code Manager** on page 55
  Set up your control repo, create a Puppetfile, and configure Code Manager so you can start adding content to your PE environments.
  - **Manage Apache configuration on *nix targets** on page 59
  - **Manage IIS configuration on Windows targets** on page 64
  - **Next steps** on page 70
Now that you have set up some basic automated configuration management with PE, here are some things to do next:

### Install PE

Installing PE sets up a standard installation, which you can use to try out PE with up to 10 nodes or to manage up to 4,000 nodes.

Ensure your system capacity can manage a PE installation by reviewing the [hardware requirements for standard installations](#).
A standard PE installation consists of these components installed on a single node:

- The master: the central hub of activity, where Puppet code is compiled to create agent catalogs, and where SSL certificates are verified and signed.
- The console: the graphical web interface, which features configuration and reporting tools.
- PuppetDB: the data store for data generated throughout your Puppet infrastructure.

**Important:** The Puppet master runs only on *nix machines. Windows machines can run as Puppet agents, and you can manage them with your *nix Puppet master. If you want to operate a *nix master remotely from a Windows machine, before installing PE, configure an SSH client, such as PuTTY, with the hostname or IP address and port of the *nix machine that you want to install as your master. When you open an SSH session to install the *nix master, log in as the root user.

**Install PE**

Installation uses default settings to install all of the PE infrastructure components on a single node. After installing, you can scale or customize your installation as needed.

**Important:** Perform these steps on your target master node logged in as root. If you're installing on a system that doesn't enable root login, switch to the root user with this command: `sudo su -`

1. Download the tarball appropriate to your operating system and architecture.
   
   **Tip:** To download packages from the command line, run `wget --content-disposition <URL>` or `curl -JLO <URL>`, using the URL for the tarball you want to download.

2. Unpack the installation tarball:

   ```bash
tar -xf <TARBALL_FILENAME>
```

3. From the installer directory, run the installer:

   ```bash
./puppet-enterprise-installer
```

4. When prompted, specify a console administrator password: `puppet infrastructure console_password --password=<MY_PASSWORD>

5. Run Puppet twice: `puppet agent -t`.

6. Optional: Restart the shell in order to use client tool commands.

**Log into the PE console**

The console is a graphical interface where you can manage your infrastructure without relying on the command line.

To log in for the first time:

1. Open the console by entering the URL `<master_certname>` into your browser, where master_certname is the trusted certificate name of your master.

   **Note:** You’ll receive a browser warning about an untrusted certificate because you were the signing authority for the console’s certificate, and your Puppet Enterprise deployment is not known to your browser as a valid signing authority. Ignore the warning and accept the certificate.

2. On the login page for the console, log in with the user name `admin` and the password you created when installing. Keep track of this login as you will use it later.

Next, check the status of your PE master.

**Check the status of your master**

You can run a task to check the status of your master in the console.

A task is a single action that allows you to do ad-hoc things like upgrade packages and restart services on target machines. PE comes with a few tasks installed, such as `package`, `service`, and `puppet_conf`, and you can download more tasks from the Forge or write your own.
1. In the console, in the **Orchestration** section, click **Tasks**.
2. Click **Run a task** in the upper right corner of the **Tasks** page.
3. In the **Task** field, select **service** because you are checking the status of the master service.
4. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.
5. Under **Task parameters**, parameters and values for the task. The **service** task has two required parameters. For **action**, choose **status**. For **name**, enter **puppet**.
6. Under **Select targets**, select **Node list**.
   a) In the **Inventory nodes** field, add the hostname of your master and select it.
7. Click **Run task** or **Schedule job**.

Your task run appears on the **Tasks** page. Click the **ID** number to view the results and output.

**Tip:** Filter run results by task name to find specific task runs.

View the task status and output in the **Jobs** page when it is finished running.

The status of your master should be “running” and “enabled”. To learn more about tasks, including how to install them from the Forge or how to write your own, visit the **Installing tasks** and **Writing tasks** sections of the docs.

Next, use the console to add nodes to your inventory.

### Add nodes to the inventory

Your inventory is the list of nodes managed by Puppet. Add nodes with agents, agentless nodes that connect over SSH or WinRM, or add network devices like network switches and firewalls. Agent nodes help keep your infrastructure in your desired state. Agentless nodes do not have an agent installed, but can do things like run tasks and plans.

### Add agent nodes

Use the console to add agent nodes to your inventory. Agents help with configuration management by periodically correcting changes to resources and reporting information to the master about your infrastructure. Note that adding an agent node installs the agent on the node.

1. In the console, on the **Nodes** page, click **Add nodes**.
2. Click **Install agents**.
3. Select the transport method. This connection is used to remotely install the agent on the target node.
   - **SSH** for *nix targets
   - **WinRM** for Windows targets
4. Enter the target host names and the credentials required to access them. If you use an SSH key, include begin and end tags.
5. Click **Add nodes**.

**Tip:** Click **Installation job started** to view the job details for the task.

Agents are installed on the target nodes and then automatically submit certificate signing requests (CSR) to the master. The list of unsigned certificates is updated with new targets.

### Add agentless nodes

Add nodes that will not or cannot have an agent installed on them. Agentless automation allows you to do things like update a package or restart a server on demand for node targets that don't have software installed.

1. In the console, on the **Nodes** page, click **Add nodes**.
2. Click **Connect over SSH or WinRM**.
3. Select a transport method.
   - SSH for *nix targets
   - WinRM for Windows targets

4. Enter target host names and the credentials required to access them. If you use an SSH key, include begin and end tags.

5. Optional: Select additional target options. For example, to add a target port number, select Target Port from the drop-down list, enter the number, and click Add. For details, see Transport configuration options on page 291.

6. Click Add nodes.

After the nodes have been added to the inventory, they are added to PuppetDB, and you can view them from the Nodes page. Nodes in the inventory can be added to an inventory node list when you set up a job to run tasks. To review each inventory node's connection options, or to remove the node from inventory, go to the Connections tab on the node's details page.

Managing certificate signing requests in the console

A certificate signing request appears in the console on the Unsigned certs page after you add an agent node to inventory. Accept or reject submitted requests individually or in a batch.

- To manage requests individually, click Accept or Reject.
- To manage the entire list of requests, click Accept All or Reject All. Nodes are processed in batches. If you close the browser window or navigate to another website while processing is in progress, only the current batch is processed.

After you accept the certificate signing request, the node appears in the console after the next Puppet run. To make a node available immediately after you approve the request, run Puppet on demand.

Related information
Running Puppet on demand on page 441

The orchestrator gives you the ability to set up jobs in the console or on the command line to trigger on-demand Puppet runs.

Add code and set up Code Manager

Set up your control repo, create a Puppetfile, and configure Code Manager so you can start adding content to your PE environments.

The control repo is where you store your code. Code in your control repo is usually bundled in modules.

The Puppetfile specifies detailed information about each environment's Puppet code and data, including where to get that code and data from, where to install it, and whether to update it.

Code Manager automates the management and deployment of your Puppet code. It isn't required to use PE, but it is helpful for ensuring Puppet syncs code to your masters and all your server run new code at the same time.

Create a control repo from the Puppet template

To create a control repo that includes a standard recommended structure, code examples, and configuration scripts, base your control repo on the Puppet control repo template. This template covers most customer situations.

To base your control repo on the Puppet control repository template, you copy the control repo template to your development workstation, set your own remote Git repository as the default source, and then push the template contents to that source.

The control repo template contains the files needed to get you started with a functioning control repo, including:

- An environment.conf file to implement a site-modules/ directory for roles, profiles, and custom modules.
- config_version scripts to notify you which control repo version was applied to the agents.
- Basic code examples for setting up roles and profiles.

© 2020 Puppet, Inc.
• An example hieradata directory that matches the default hierarchy.
• A Puppetfile to manage content maintained in your environment.

Set up a private SSH key so that your master can identify itself to your Git host.

1. Generate a private SSH key to allow access to the control repository.

   This SSH key cannot require a password.

   a) Generate the key pair:

   ```
   ssh-keygen -t rsa -b 2048 -P '' -f /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   ```

   b) Set appropriate permissions so that the pe-puppet user can access the key:

   ```
   puppet infrastructure configure
   ```

   Your keys are now located in /etc/puppetlabs/puppetserver/ssh:

   • Private key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   • Public key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa.pub

   Configure your Git host to use the SSH public key you generated. The process to do this is different for every Git host. Usually, you create a user or service account, and then assign the SSH public key to it.

   Code management needs read access to your control repository, as well as any module repositories referenced in the Puppetfile.

   See the your Git host docs for detailed instructions on adding SSH keys to your Git server. Commonly used Git hosts include:

   • GitHub
   • BitBucket Server
   • GitLab

2. Create a repository in your Git account, with the name you want your control repo to have.

   Steps for creating a repository vary, depending on what Git host you are using (GitHub, GitLab, Bitbucket, or another provider). See your Git host's documentation for complete instructions.

   For example, on GitHub:

   a) Click + at the top of the page, and choose New repository.
   b) Select the account Owner for the repository.
   c) Name the repository (for example, control-repo).
   d) Note the repository's SSH URL for later use.

3. If you don't already have Git installed, run the following command on your master:

   ```
   yum install git
   ```

4. From the command line, clone the Puppet control-repo template.

   ```
   git clone https://github.com/puppetlabs/control-repo.git
   ```

5. Change directory into your contro repo.

   ```
   cd <NAME OF YOUR CONTROL REPO>
   ```

6. Remove the template repository as your default source.

   ```
   git remote remove origin
   ```
7. Add the control repository you created as the default source.

   `git remote add origin <URL OF YOUR GIT REPOSITORY>`

8. Push the contents of the cloned control repo to your remote copy of the control repo:

   `git push origin production`

You now have a control repository based on the Puppet `control-repo` template. When you make changes to this repo on your workstation and push those changes to the remote copy of the control repo on your Git server, Code Manager deploys your infrastructure changes.

You also now have a Puppetfile available for you to start adding and managing content, like module code.

**Configure Code Manager**

Code Manager stages, commits, and synchronizes your code, automatically managing your environments and modules when you make changes.

**Enable Code Manager**

To enable Code Manager set parameters in the console.

**Before you begin**

See the Configure settings using the console on page 151 documentation to learn how to set parameters in the console.

1. In the console, click **Node groups**, set the following parameters in the `puppet Enterprise::profile::master` class in the PE Master node group.

   - `code_manager_auto_configure` to `true`.
   - `r10k_remote`: This is the location of your control repository. Enter a string that is a valid URL for your Git control repository. For example: `git@<YOUR.GIT.SERVER.COM>:puppet/control.git`.
   - `r10k_private_key`: Enter a string specifying the path to the SSH private key that permits the pe-puppet user to access your Git repositories. This file must be located on the master, owned by the pe-puppet user, and located in a directory that the pe-puppet user has permission to view. We recommend `/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa`

2. Click **Commit**.

3. On the command line, run `puppet job run --nodes <NODE NAME>` where `<NODE NAME>` is the name of your master.

   `puppet job run --nodes small-doubt.delivery.puppetlabs.net`

   **Note:** r10k is a code management tool that allows you to manage your environment configurations — production, testing, and development — in a source control repository.

   Next, test the connection to the control repo.

**Set up authentication for Code Manager**

To securely deploy environments, Code Manager needs an authentication token for both authentication and authorization.

**Before you begin**

If you would like to use PE client tools, configure these now. PE client tools let you access PE services from a workstation that is not necessarily managed by Puppet. They come pre-installed on your master, but you need to configure them by creating a configuration file. See Configuring PE client tools for more information.

To generate a token for Code Manager, first assign a user to the deployment role, and then request an authentication token.
Assign a user to the deployment role
To request an authentication token, you must first assign a user the correct permissions with role-based access control (RBAC).

1. In the console, create a deployment user. We recommend that you create a dedicated deployment user for Code Manager use.
2. Add the deployment user to the Code Deployers role. This role is automatically created on install, with default permissions for code deployment and token lifetime management.
3. Create a password by clicking Generate Password.

Request the authentication token.

Generate the authentication token using the puppet-access command.

1. From the command line on the master, run puppet-access login --lifetime 180d. This command both requests the token and sets the token lifetime to 180 days.
   
   Tip: You can add flags to the request specifying additional settings such as the token file's location or the URL for your RBAC API. See Configuration file settings for puppet-access.
2. Enter the username and password of the deployment user when prompted.

The generated token is stored in a file for later use. The default location for storing the token is ~/.puppetlabs/token. To view the token, run puppet-access show.

Test the connection to the control repo.

Generate a token for use by a service on page 211
If you need to generate a token for use by a service and the token doesn't need to be saved, use the --print option.

Deploy your code
Use the command line to trigger Code Manager after making changes to your Puppetfile.

When you make changes to your Puppetfile, like adding a new module or creating a repo, you must deploy your code before Code Manager can recognize or start managing the content.

SSH into your master and run puppet-code deploy --all --wait.
You have deployed code to all environments. The --wait flag returns results after the deployment is finished. Use the command `puppet-code deploy <ENVIRONMENT>` to deploy code to only a specific environment. You can also deploy code using a webhook or custom scripts.

Manage Apache configuration on *nix targets

- **Add a module** on page 59
  Modules are self-contained, shareable bundles of code and data. Each module manages a specific task in your infrastructure, like installing and configuring a piece of software. You can write your own modules or download pre-built modules from the Forge. While you can use any module available on the Forge, PE customers can take advantage of supported modules. These modules are designed to make common services easier, and are tested and maintained by Puppet. A lot of your infrastructure will be supported by modules, so it is important to learn how to install, build, and use them.
- **Configure your desired state** on page 60
  Tell PE how your infrastructure should be configured by grouping and classifying nodes based on their function. Before you begin, think of which of your inventory nodes you want to configure with Apacheservices.
- **Organize webserver configurations with roles and profiles** on page 61
  The roles and profiles method is a reliable way to build reusable, configurable, and refactorable system configurations.

Add a module

Modules are self-contained, shareable bundles of code and data. Each module manages a specific task in your infrastructure, like installing and configuring a piece of software. You can write your own modules or download pre-built modules from the Forge. While you can use any module available on the Forge, PE customers can take advantage of supported modules. These modules are designed to make common services easier, and are tested and maintained by Puppet. A lot of your infrastructure will be supported by modules, so it is important to learn how to install, build, and use them.

Install the apache module

To get you started working with modules, install the puppetlabs/apache module, which automates installing, configuring, and managing Apache services.

**Before you begin**

These instructions assume you’ve installed PE and at least one *nix agent node.

1. Go to the [apache module in the Forge](https://forge.puppet.com/modules/apache).
2. Follow the instructions in the [r10k or Code Manager](https://forge.puppet.com/modules/code_manager) drop down to add the module declaration to your Puppetfile.

   If you don’t specify options, Code Manager installs the latest version and does not update it automatically. To always have the latest version installed, specify :latest and it will update automatically when a new version is released. To install a specific version of the module that does not update automatically, specify the version number as a string.

   For example, to install version 5.4.0 of the apache module that will not update, and its dependencies, use the following code:

   ```
   mod 'puppetlabs/apache', '5.4.0'
   mod 'puppetlabs/stdlib', '4.13.1'
   mod 'puppetlabs/concat', '2.2.1'
   
   The puppetlabs/stdlib and puppetlabs/concat modules are dependencies of the Apache module. You can see the dependencies for each module by clicking the Dependencies tab on a module’s Forge page.
   ```
3. SSH into your master and deploy code by running the `puppet-code deploy --all` command.

© 2020 Puppet, Inc.
You have just installed a Puppet module!

**View the apache task in the console**
When you successfully install a module, you can start running tasks that are included in the module from the console. The puppetlabs/apache module contains a task that allows you to perform apache service functions.

To see the task in the console:

In the **Run** section, under **Task**, type **apache** in the **Task** field.

You can now run the **apache** task.

If you don't see the **apache** task, try refreshing the console in the browser. If it still does not populate, double check the puppetlabs/apache module is in your Puppetfile and try again.

**Configure your desired state**
Tell PE how your infrastructure should be configured by grouping and classifying nodes based on their function. Before you begin, think of which of your inventory nodes you want to configure with Apache services.

**Create your classification group**
Create a classification node group. This is a parent group to other node groups you create that contain classification data. You only need to set this up one time.

1. In the console, click **Node groups**, and click **Add group**.
2. Specify options for the new node group:
   - **Parent name**: All Nodes
   - **Group name**: All Classification
   - **Environment**: production
   - **Environment group**: do not select
3. Click **Add**.

You have added a classification group. Next, create a node group and add it as a child of this classification group.

**Create your apache node group**
After you create your parent classification group, make the **apache** node group a child of it.

1. In the console, click **Node groups**, and click **Add group**.
2. Specify options for the new node group:
   - **Parent name**: All Classification
   - **Group name**: apache
   - **Environment**: production
   - **Environment group**: do not select
3. Click **Add**.

You now have a node group for nodes you want to configure Apache on. Next, determine which nodes from your inventory you want to run Apache on and add them to the **apache** node group.

**Add nodes to the apache node group**
Once you determine which nodes from your inventory should be in your **apache** node group, pin the nodes to the group. Pinning allows you to add nodes to a group one at a time. You can also dynamically add nodes to a node group based on rules you set in the console, which is helpful for large inventories.

If you are stuck on deciding which nodes should be in your **apache** node group, read about **Best practices for classifying node groups** on page 296.

1. In the console, click **Node groups** and select the **apache** node group you just created.
2. On the **Rules** tab, under **Certname**, enter the certname of a node you want to add to the **apache** node group.
3. Click **Pin node**.
4. Repeat for additional nodes you want to add to the **apache** group.
5. When you are done pinning nodes, commit changes.

You have added your **apache** nodes into a node group. For more information on adding and classifying nodes, read about **Making changes to node groups** on page 303 and **Grouping and classifying nodes** on page 296.

**Run Puppet on your Apache nodes**

Run Puppet in the console to enforce your desired state on the **apache** node group you created.

1. In the console, on the **Jobs** page, click **Run Puppet**.
2. Under **Run options**, do not select anything.
3. From the list of target types, select **Node group**.
4. In the **Chose a node group box**, search for the **apache** node group and click **Select**.
5. Click **Run job**.

View the job status and a list of previous Puppet jobs on the **Jobs** page.

Congratulations! You have run Puppet on your **apache** node group. In the future, the **apache** nodes will check in with PE every 30 minutes to confirm that their **apache** configuration matches what you've specified, and PE will correct it if it doesn't.

Next, learn how to use roles and profiles to efficiently manage system configurations.

**Organize webserver configurations with roles and profiles**

The **roles and profiles** method is a reliable way to build reusable, configurable, and refactorable system configurations.

Roles and profiles help you pick out relevant pieces of code from modules and bundle them together to create your own custom set of code for managing things. **Profiles** are the actual bundles of code. **Roles** gather profiles together so that you can assign them to nodes. This allows you to efficiently organize your Puppet code.

To learn about roles and profiles by example, follow these instructions to define a profile that configures virtual webhost (vhost) to serve the **example.com** website and include a firewall rule. Then, you will create a role to contain the profile, and you'll assign it to a the **apache** node group that you created earlier. This lays down a base structure where, if you had additional websites to serve, you would create additional profiles for them, and those profiles could be separated or combined inside the roles as needed.

Because you are adding a firewall rule, make sure you add the **puppetlabs/firewall** module to your Puppetfile, following the same process you used to add the **apache** module. Remember to add the firewall modules dependencies — **puppetlabs-stdlib**.

```bash
mod 'puppetlabs/firewall', '2.3.2'
mod 'puppetlabs/stdlib', '4.0.0'
```

See **The roles and profiles method** on page 333 for more context on how roles and profiles work.

**Set up your prerequisites**

Before you begin writing content for roles and profiles, you need to create modules to store them in.

1. Create one module for **profile** and one for **role** directly in your control repo. Do not put them in your Puppetfile.
2. Make a new directory in the repo named **site**. For example, /etc/puppetlabs/code/environments/production/site.
3. Edit the **environment.conf** file to add **site** to the modulepath. This is the place where Puppet looks for module information. For example: `modulepath = site:modules:$basemodulepath`.
4. Put the **role** and **profile** modules in the **site** directory.
Write a profile for your Apache vhost

Write a webserver profile that includes rules for your Apache vhost and firewall.

Before you begin

Make sure you have already installed the puppetlabs/apache module and the puppetlabs/firewall module from the forge.

Note: We recommend writing your code in a code editor, such as VSCode, and then pushing to your Git server. Puppet has an extension for VSCode that supports syntax highlighting of the Puppet language.

1. In the profile module you added, create the following directory:
   - manifests/
     - webserver/
       - example.pp

2. Paste the following Puppet code into the new example.pp file:

```puppet
# /etc/puppetlabs/code/environments/production/site/profile/manifests/webserver/example.pp
class profile::webserver::example (
  String $content = "Hello from vhost\n",
  Array[String] $ports = ['80'],
  Array[String] $ips = ['127.0.0.1', '127.0.0.2'],
) {
  class { 'apache':
    default_vhost => false,
  }
  apache::vhost { 'example.com':
    port => $ports,
    ip => $ips,
    ip_based => true,
    docroot => '/var/www/html',
  }
  file { '/var/www/html/index.html':
    ensure => file,
    content => $content,
  }
  firewall { '100 allow http and https access':
    dport => $ports,
    proto => tcp,
    action => accept
  }
}
```

This profile applies custom rules for the apache::vhost class that include arrays of $ports and $ips. The code uses file to ensure there is content on the main page of your vhost. Finally, there is a firewall rule that only allows traffic from the port or ports set in the $ports array.

You can add your own code to the profile as needed. Look at the readme and reference sections for the puppetlabs/apache and puppetlabs/firewall modules in the Forge for more content.

Set data for the profile

Hiera is a configuration method that allows you to set defaults in your code, or override those defaults in certain circumstances. Use it to fine-tune data within your profile.

Suppose you want to use the custom fact stage to represent the deployment stage of the node, which can be dev, test, or prod. For this example, use dev and prod.

With Hiera structured data, you can set up a four-layer hierarchy that consists of the following:
• `console_data` for data defined in the console.
• `nodes/%{trusted.certname}` for per-node overrides.
• `stage/%{facts.stage}` for setting stage-specific data.
• `common` for global fallback data.

This structure lets you tune the settings for ports and IPs in each stage.

For example, to configure webservers in the development environment to have a custom message and to use port 8080, you’d create a data file with the following name, location, and code content:

```yaml
# cat /etc/puppetlabs/code/environments/production/data/stage/dev.yaml
---
profile::webserver::example::content: "Hello from dev\n"
profile::webserver::example::ports:
  - '8080'
```

To have webservers in the production environment listen to all interfaces:

```yaml
# cat /etc/puppetlabs/code/environments/production/data/stage/prod.yaml
---
profile::webserver::example::ips:
  - '0.0.0.0'
  - '::'
```

This is the briefest of introductions to all the things you can do with structured data in Hiera. To learn more about setting up hierarchical data, see Getting started with Hiera.

**Write a role for your Apache web server**

To write roles, think about what machines you’ll be managing and decide what else they need in addition to the `webserver` profile.

Say you want all of the nodes in your `apache` node group to use the profile you just wrote. Suppose also that your organization assigns all machines, including workstations, with a profile called `profile::base`, which manages basic policies and uses some conditional logic to include operating-system-specific configuration.

Inside the following file in your control repo:

```
/etc/puppetlabs/code/environments/production/site/role/manifests/exampleserver.pp
```

Write a role that includes both the `base` profile and your `webserver` profile:

```ruby
class role::exampleserver {
  include profile::base
  include profile::webserver
}
```

You can add more profiles to this role, or create additional roles with more profile configurations based on your needs.

**Assign the role to nodes**

Assign the `exampleserver` role to nodes where you want to manage the configuration of the Apache vhost, based on what you wrote in the `webserver::example` profile.

For this example, assume you want to add `role::exampleserver` to all the nodes in the `apache` node group you created.

1. In the console, click **Node groups** and select the `apache` node group.
2. On the **Classes** tab, select `role::exampleserver` and click **Add class**.
3. Commit the change.
Your apache node group is managing your Apache vhost based on the rules you coded into your webserver profile.

Manage IIS configuration on Windows targets

- **Add a module** on page 59
  Modules are self-contained, shareable bundles of code and data. Each module manages a specific task in your infrastructure, like installing and configuring a piece of software. You can write your own modules or download pre-built modules from the Forge. While you can use any module available on the Forge, PE customers can take advantage of supported modules. These modules are designed to make common services easier, and are tested and maintained by Puppet. A lot of your infrastructure will be supported by modules, so it is important to learn how to install, build, and use them.

- **Configure your desired state** on page 65
  Tell PE how your infrastructure should be configured by grouping and classifying nodes based on their function. Before you begin, think of which of your inventory nodes you want to configure with IIS services.

- **Organize webserver configurations with roles and profiles** on page 66
  The roles and profiles method is a reliable way to build reusable, configurable, and refactoring system configurations.

**Add a module**

Modules are self-contained, shareable bundles of code and data. Each module manages a specific task in your infrastructure, like installing and configuring a piece of software. You can write your own modules or download pre-built modules from the Forge. While you can use any module available on the Forge, PE customers can take advantage of supported modules. These modules are designed to make common services easier, and are tested and maintained by Puppet. A lot of your infrastructure will be supported by modules, so it is important to learn how to install, build, and use them.

**Install the IIS module**

To get you started working with modules, install the puppetlabs/iis module, which automates installing, configuring, and managing IIS services.

Before you begin

These instructions assume you’ve installed PE and at least one Windows agent node.

1. Go to the IIS module in the Forge.

2. Follow the instructions in the r10k or Code Manager drop down to add the module declaration to your Puppetfile.

   If you don’t specify options, Code Manager installs the latest version and does not update it automatically. To always have the latest version installed, specify :latest and it will update automatically when a new version is released. To install a specific version of the module that does not update automatically, specify the version number as a string.

   For example, to install version 7.0.0 of the IIS module that will not update, and its dependencies, use the following code:

   ```
   mod 'puppetlabs/iis, '7.0.0'
   mod 'puppetlabs/pwshlib', '0.4.0'
   ```

   The puppetlabs/pwshlib module is a dependency of the IIS module. You can see the dependencies for each module by clicking the Dependencies tab on a module’s Forge page.

3. SSH into your master and deploy code running the puppet-code deploy --all command.

You have just installed a Puppet module!
Configure your desired state

Tell PE how your infrastructure should be configured by grouping and classifying nodes based on their function. Before you begin, think of which of your inventory nodes you want to configure with IIS services.

Create your classification group

Create a classification node group. This is a parent group to other node groups you create that contain classification data. You only need to set this up one time.

1. In the console, click Node groups, and click Add group.
2. Specify options for the new node group:
   - Parent name: All Nodes
   - Group name: All Classification
   - Environment: production
   - Environment group: do not select
3. Click Add.

You have added a classification group. Next, create a node group and add it as a child of this classification group.

Create your iis node group

After you create your parent classification group, make the iis node group a child of it.

1. In the console, click Node groups, and click Add group.
2. Specify options for the new node group:
   - Parent name: All Classification
   - Group name: iis
   - Environment: production
   - Environment group: do not select
3. Click Add.

You now have a node group for nodes you want to configure IIS on. Next, determine which nodes from your inventory you want to run IIS on and add them to the iis node group.

Add nodes to the iis node group

Once you determine which nodes from your inventory should be in your iis node group, pin the nodes to the group. Pinning allows you to add nodes to a group one at a time. You can also dynamically add nodes to a node group based on rules you set in the console, which is helpful for large inventories.

If you are stuck on deciding which nodes should be in your iis node group, read about Best practices for classifying node groups on page 296.

1. In the console, click Node groups and select the iis node group you just created.
2. On the Rules tab, under Certname, enter the certname of a node you want to add to the iis node group.
3. Click Pin node.
4. Repeat for additional nodes you want to add to the iis group.
5. When you are done pinning nodes, commit changes.

You have added your iis nodes into a node group. For more information on adding and classifying nodes, read about Making changes to node groups on page 303 and Grouping and classifying nodes on page 296.

Run Puppet on your IIS nodes

Run Puppet in the console to enforce your desired state on the iis node group you created.

1. In the console, on the Jobs page, click Run Puppet.
2. Under Run options, do not select anything.
3. From the list of target types, select Node group.
4. In the Chose a node group box, search for the iis node group and click Select.

5. Click Run job.

View the job status and a list of previous Puppet jobs on the Jobs page.

Congratulations! You have run Puppet on your iis node group. In the future, the IIS nodes will check in with PE every 30 minutes to confirm that their IIS configuration matches what you've specified, and PE will correct it if it doesn't.

Next, learn how to use roles and profiles to efficiently manage system configurations.

Organize webservers configurations with roles and profiles

The roles and profiles method is a reliable way to build reusable, configurable, and refactorable system configurations.

Roles and profiles help you pick out relevant pieces of code from modules and bundle them together to create your own custom set of code for managing things. Profiles are the actual bundles of code. Roles gather profiles together so that you can assign them to nodes. This allows you to efficiently organize your Puppet code.

To learn about roles and profiles by example, follow these instructions to define a profile that configures the example.com website and includes a firewall rule. Then, you will create a role to contain the profile, and you'll assign it to the iis node group that you created earlier. This lays down a base structure where, if you had additional websites to serve, you would create additional profiles for them, and those profiles could be separated or combined inside the roles as needed.

Note: Adding a firewall rule isn’t necessary for an IIS website because the port is already open, but the purpose of this example is to show that you can write a role that manages more than one piece of software to accomplish a task. The webservers role can manage both IIS and the firewall.

Because you are adding a firewall rule, make sure you add the puppet/windows_firewall module to your Puppetfile, following the same process you used to add the iis module. Remember to add the firewall modules dependencies — puppetlabs/stdlib and puppetlabs/registry.

```
mod 'puppet/windows_firewall', '2.0.2'
mod 'puppetlabs/stdlib', '4.6.0'
mod 'puppetlabs/registry', '1.1.1'
```

See The roles and profiles method on page 333 for more context on how roles and profiles work.

Set up your prerequisites

Before you begin writing content for roles and profiles, you need to create modules to store them in.

1. Create one module for profile and one for role directly in your control repo. Do not put them in your Puppetfile.
2. Make a new directory in the repo named site. For example, /etc/puppetlabs/code/environments/production/site.
3. Edit the environment.conf file to add site to the modulepath. This is the place where Puppet looks for module information. For example: modulepath = site:modules:$basemodulepath.
4. Put the role and profile modules in the site directory.

Write a profile for your IIS website

Write a webserver profile that includes rules for your iis_site and firewall.

Before you begin

Make sure you have already installed the puppetlabs/iis module and the puppet/windows_firewall module from the Forge.

Note: We recommend writing your code in a code editor, such as VSCode, and then pushing to your Git server. Puppet has an extension for VSCode that supports syntax highlighting of the Puppet language.
1. In the profile module you added, create the following directory:
   - manifests/
     - webserver/
       - example.pp
2. Paste the following Puppet code into the new example.pp file:

```puppet
class profile::webserver::example {
  String $content = 'Hello from iis',
  String $port = '80',
}

windows_firewall::exception { 'http':
  ensure       => present,
  direction    => 'in',
  action       => 'allow',
  enabled      => true,
  protocol     => 'TCP',
  local_port   => Integer($port),
  remote_port  => 'any',
  display_name => 'IIS incoming traffic HTTP-In',
  description  => "Inbound rule for IIS web traffic. [TCP ${port}]",
}

$iis_features = ['Web-WebServer', 'Web-Scripting-Tools', 'Web-Mgmt-Console']
iis_feature { $iis_features:
  ensure => 'present',
}

# Delete the default website to prevent a port binding conflict.
iis_site {'Default Web Site':
  ensure  => absent,
  require => Iis_feature['Web-WebServer'],
}
iis_site { 'minimal':
  ensure   => 'started',
  physicalpath => 'c:\inetpub\minimal',
  applicationpool => 'DefaultAppPool',
  bindings => [
    {
      'bindinginformation' => '${facts['ipaddress']}:${port}:'
    },
    'protocol' => 'http',
  ],
  require => [
    File['minimal-index'],
    Iis_site['Default Web Site']
  ],
}

file { 'minimal':
  ensure => 'directory',
  path => 'c:\inetpub\minimal',
}

file { 'minimal-index':
  ensure  => 'file',
  path    => 'c:\inetpub\minimal\index.html',
  content => $content,
  require => File['minimal']
}
}
```

This profile applies custom rules for the `iis_site` class that include settings for `$port` and `$content`. The code uses `file` to ensure there is content on the main page of your site. Finally, there is a firewall rule that only allows traffic from the port or ports set in the `$port` setting.

You can add your own code to the profile as needed. Look at the Readme and Reference sections for the `puppetlabs/iis` and `puppet/windows_firewall` modules in the Forge for more content.
**Set data for the profile**

Hiera is a configuration method that allows you to set defaults in your code, or override those defaults in certain circumstances. Use it to fine-tune data within your profile.

Suppose you want to use the custom fact `stage` to represent the deployment stage of the node, which can be `dev`, `test`, or `prod`. For this example, use `dev` and `prod`.

With Hiera structured data, you can set up a four-layer hierarchy that consists of the following:

- `console_data` for data defined in the console.
- `nodes/%{trusted.certname}` for per-node overrides.
- `stage/%{facts.stage}` for setting stage-specific data.
- `common` for global fallback data.

This structure lets you tune the settings for ports and IPs in each stage.

For example, to configure webservers in the development environment to have a custom message and to use port 8080, you'd create a data file with the following name, location, and code content:

```yaml
# /etc/puppetlabs/code/environments/production/data/stage/dev.yaml
---
profile::webserver::example::content: "Hello from dev"
profile::webserver::example::ports:
  - '8080'
```

To have webservers in the production environment listen to all interfaces:

```yaml
# /etc/puppetlabs/code/environments/production/data/stage/prod.yaml
---
profile::webserver::example::ips:
  - '0.0.0.0'
  - '::'
```

This is the briefest of introductions to all the things you can do with structured data in Hiera. To learn more about setting up hierarchical data, see Getting started with Hiera.

**Write a role for your IIS website**

To write roles, think about what machines you'll be managing and decide what else they need in addition to the `webserver` profile.

Say you want all of the nodes in your `iis` node group to use the profile you just wrote. Suppose also that your organization assigns all machines, including workstations, with a profile called `profile::base`, which manages basic policies and uses some conditional logic to include operating-system-specific configuration.

Inside the following file in your control repo:

```bash
site-modules\role\manifests\exampleserver.pp
```

Write a role that includes both the `base` profile and your `webserver` profile:

```perl
class role::exampleserver {
  include profile::base
  include profile::webserver
}
```

You can add more profiles to this role, or create additional roles with more profile configurations based on your needs.
Assign the role to nodes
Assign the exampleserver role to nodes where you want to manage the configuration of the iis_site, based on what you wrote in the webserver::example profile.

For this example, assume you want to add role::exampleserver to all the nodes in the iis node group you created.

1. In the console, click Node groups and select the iis node group.
2. On the Classes tab, select role::exampleserver and click Add class.
3. Commit the change.

Your iis node group is managing your iis_site website based on the rules you coded into your webserver profile.

Next steps
Now that you have set up some basic automated configuration management with PE, here are some things to do next:

- Check out the Forge to download additional modules and start managing other things like NTP or machines running on Azure.
- Learn how to develop high-quality modules with the Puppet VSCode extension and Puppet Development Kit (PDK).
- See the Configuring Puppet Enterprise on page 150 docs to fine-tune things like the console performance, orchestration services, Java, and proxy settings.
- Learn more about running Tasks and plans in PE on page 458, or write your own; see Writing tasks on page 477 and Writing plans on page 494.
- See Managing access on page 193 for information about adding and organizing other PE users and their permissions.
- If you have teams rolling out Puppet code changes across your infrastructure, check out Getting Started with Continuous Delivery for Puppet Enterprise.
- Check out our Youtube channel to learn more about Puppet.

Installing
A Puppet Enterprise deployment typically includes infrastructure components and agents, which are installed on nodes in your environment.

You can install infrastructure components in multiple configurations and scale up with compilers. You can install agents on *nix, Windows, and macOS nodes.
Choosing an architecture

There are several configurations available for Puppet Enterprise. The configuration you use depends on the number of nodes in your environment and the resources required to serve agent catalogs. All PE installations begin with the standard configuration, and scale up by adding additional components as needed.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Description</th>
<th>Node limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard installation</td>
<td>All infrastructure components are installed on the master. This installation type is the easiest to install, upgrade, and troubleshoot.</td>
<td>Up to 4,000</td>
</tr>
<tr>
<td>(Recommended)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Large installation</td>
<td>Similar to a standard installation, plus one or more compilers and a load balancer which help distribute the agent catalog compilation workload.</td>
<td>4,000–20,000</td>
</tr>
<tr>
<td>Extra-large installation</td>
<td>Similar to a large installation, plus a separate node which hosts the PE-PostgreSQL instance.</td>
<td>More than 20,000</td>
</tr>
</tbody>
</table>

Tip: You can add disaster recovery to an installation with or without compilers by configuring a replica of your master. Disaster recovery isn't supported with standalone PE-PostgreSQL.
Standard installation

Large installation
**System requirements**

Refer to these system requirements for Puppet Enterprise installations.

- **Hardware requirements** on page 73
  These hardware requirements are based on internal testing at Puppet and are meant only as guidelines to help you determine your hardware needs.

- **Supported operating systems** on page 77
  Puppet Enterprise supports various operating systems depending on the role a machine assumes in your infrastructure.

- **Supported browsers** on page 83
  The following browsers are supported for use with the console.

- **System configuration** on page 83
  Before installing Puppet Enterprise, make sure that your nodes and network are properly configured.

**Hardware requirements**

These hardware requirements are based on internal testing at Puppet and are meant only as guidelines to help you determine your hardware needs.

Your installation’s existing code base can significantly affect performance, so adjusting expectations based on differences between your installation’s code base and the testing code base as documented in How we develop hardware requirements is important to make the best use of the requirements on this page.

**Related information**

- **Methods for configuring Puppet Enterprise** on page 151
  After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

- **Tuning standard installations** on page 172
Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

**Hardware requirements for standard installations**

In standard installations, hardware requirements differ depending on the number of nodes you’re managing. To take advantage of progressively larger hardware, you must configure your environment to use additional resources.

<table>
<thead>
<tr>
<th>Node volume</th>
<th>Cores</th>
<th>RAM</th>
<th>/opt/</th>
<th>/var/</th>
<th>AWS EC2</th>
<th>Azure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trial use</td>
<td>2</td>
<td>8 GB</td>
<td>20 GB</td>
<td>24 GB</td>
<td>m5.large</td>
<td>A2 v2</td>
</tr>
<tr>
<td>Up to 2,000</td>
<td>4</td>
<td>8 GB</td>
<td>50 GB</td>
<td>24 GB</td>
<td>c5.xlarge</td>
<td>F4s v2</td>
</tr>
<tr>
<td>Up to 3,500</td>
<td>8</td>
<td>16 GB</td>
<td>80 GB</td>
<td>24 GB</td>
<td>c5.2xlarge</td>
<td>F8s v2</td>
</tr>
<tr>
<td>Up to 4,000</td>
<td>16</td>
<td>32 GB</td>
<td>100 GB</td>
<td>24 GB</td>
<td>c5.4xlarge</td>
<td>F16s v2</td>
</tr>
</tbody>
</table>

Important notes on the data in this chart:

- **Trial mode:** Although the m5.large instance type is sufficient for trial use, it is not supported. A minimum of four cores is required for production workloads.
- **Azure:** Azure requirements are not currently tested by Puppet, but are presented here as our best guidance based on comparable EC2 instance testing.
- **/opt/ storage requirements:** The database should not exceed 50% of /opt/ to allow for future upgrades.
- **/var/ storage requirements:** There are roughly 20 log files stored in /var/ which are limited in size to 1 GB each. Log retention settings make it unlikely that the maximum capacity will be needed, but we recommend allocating 24 GB to avoid issues.

**Hardware requirements for large installations**

If you are managing more than 4,000 nodes, you can add load-balanced compilers to your installation to increase the number of agents you can manage.

Each compiler increases capacity by approximately 1,500–3,000 nodes, until you exhaust the capacity of PuppetDB or the console, which run on the master. If you start to see performance issues around 8,000 nodes, you can adjust your hardware or move to a larger base infrastructure.

**Note:** When you expand your deployment to use compilers, you must also start using load balancers. It is simpler to upgrade your hardware in your installation, if you can, than to add compilers and load balancers.

To manage more than 4,000 nodes, we recommend the following minimum hardware:

<table>
<thead>
<tr>
<th>Node volume</th>
<th>Node</th>
<th>Cores</th>
<th>RAM</th>
<th>/opt/</th>
<th>/var/</th>
<th>EC2</th>
</tr>
</thead>
<tbody>
<tr>
<td>4,000–20,000</td>
<td>Primary node</td>
<td>16</td>
<td>32</td>
<td>150</td>
<td>10</td>
<td>c5.4xlarge</td>
</tr>
<tr>
<td></td>
<td>Each compiler</td>
<td>4</td>
<td>8</td>
<td>30</td>
<td>2</td>
<td>m5.xlarge</td>
</tr>
<tr>
<td>(1,500 - 3,000 nodes)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Hardware requirements for extra-large installations**

You can continue to expand your installation beyond 20,000 nodes by adding compilers and increasing the size of your master and PE-PostgreSQL nodes.

You can also increase the number of nodes you support by tuning certain settings such as the run interval (changing how often agents check in) and report-ttl (changing how long PuppetDB stores reports).

To manage more than 4,000 nodes, we recommend the following minimum hardware:

<table>
<thead>
<tr>
<th>Node volume</th>
<th>Node</th>
<th>Cores</th>
<th>RAM</th>
<th>/opt/</th>
<th>/var/</th>
<th>EC2</th>
</tr>
</thead>
<tbody>
<tr>
<td>20,000+</td>
<td>Primary node</td>
<td>16</td>
<td>32</td>
<td>150</td>
<td>10</td>
<td>c5.4xlarge</td>
</tr>
</tbody>
</table>

</table>

If you manage more than 20,000 nodes, contact Puppet professional services to talk about optimizing your setup for your specific requirements

**How we develop hardware requirements: Performance test methods**

Puppet tests the performance of Puppet Enterprise and develops hardware requirements based on our testing. We continue to invest in improvements in our performance testing methods.

The performance of Puppet Enterprise is highly dependent on the code base used by a specific installation. The details included here are intended to help you evaluate how your specific installation compares to what we used to generate our scale and hardware estimates so that you can better estimate what you need to manage your Puppet infrastructure.

**Tools: Gatling and puppet infrastructure tune**

We use [gatling-puppet-load-test](#), a framework we’ve developed to perform load and performance testing for PE and open source Puppet. It uses Gatling, an open source load and performance testing tool that records and replays HTTP traffic, then generates reports about the performance of the simulated requests. Using Gatling allows us to simulate agent requests in a full PE installation where Puppet Server is driving communication with PuppetDB, the node classifier, and other tools.

We also use [puppet infrastructure tune](#), which provides configuration settings to apply to the installation.

**Platform: Amazon EC2**

We use Amazon EC2 instances for our performance tests with a master node running PE and a metrics node running the simulated agents and capturing the performance data. We know that the instances’ performance varies, but this has less of an impact on overall performance than the variations in the size and complexity of users' code bases.

**Table 1: EC2 instance types**

<table>
<thead>
<tr>

<td>Scale</td>
</tr>
</tbody>
</table>

**Test environment**

**Control repository**

We use puppetlabs-pe_perf_control_repo with r10k to classify the simulated agents using roles and profiles, with three sizes defined.

**Facts and reports**

Although the simulated agents all share the same classification, we use dynamic facts and varying report responses (no change, failure, intentional change, corrective change) to better simulate a typical customer environment.
## Classification

```ruby
class role::by_size::small {
  include ::profile::tomcat::basic
  include ::profile::postgresql::basic
}
class role::by_size::medium {
  include ::role::by_size::small
  include ::profile::users
  include ::profile::sysop::packages
  include ::profile::motd
  include ::profile::hiera_check
}
class role::by_size::large {
  include ::role::by_size::medium
  include ::profile::apache::basic
  include ::profile::influxdb::basic
  include ::profile::loop_through_file_resources
}
```

## Environment cache

Although we recommend enabling environment caching to improve performance in production environments, we do not enable it in our performance testing environment to avoid unrealistic results due to the identical classification of the simulated agents.

## Fact, resource, and class counts

You can query PuppetDB using Puppet Query Language (PQL) to find the number of facts, resources, and classes for a given node.

First, you will need a token with permissions to query Puppet DB. If you don't already have one, you can generate one using `puppet-access` on the master. For example:

```
puppet-access login -l 1d
```

See our Token-based authentication on page 208 docs for more information on generating tokens.

Once you have a valid token, determine the number of facts, resources, and classes for the specified node using the example code below. In the examples, we used `perf-agent1` as the node name.

```
puppet query "facts[count()] {certname = 'perf-agent1'}"
```

```
puppet query "resources[count()] {certname = 'perf-agent1'}"
```

```
puppet query "resources[count()] {type = 'Class' and certname = 'perf-agent1'}"
```

For background and additional examples, check out this blog post or view the full PQL documentation.
Testing methodology

Warming up Puppet Server

JRuby 9000 provides better overall performance than the previous version, but it also comes with a warm-up burden. For some tests we want the Puppet Server process to be warmed up before we begin. Our warm-up process involves running a portion of the agents to generate about 300 connections to the endpoints served by JRubies, multiplied by the number of configured JRuby instances. In general, the closer you are to the node capacity of your install, the faster it will warm up when running the normal load. Our process takes about five minutes.

Apples-to-apples testing

To do an apples-to-apples test, we run a simulation for two different PE versions of 600 agents each (classified as large) checking in at the default 30-minute interval for eight iterations. We run the warm-up procedure before the simulation. Then we compare response times, system resource usage, and process resource usage. We do this on a weekly basis for all active development branches to ensure that general performance doesn’t degrade during development.

Scale testing

In order to determine the node capacity of each targeted EC2 instance type, we perform scale testing with a small load that incrementally increases the number of simulated agents until requests begin to time out or respond with errors.

The scale test is structured to simulate the default 30-minute agent check-in interval. We start the test with an agent volume below the expected performance threshold and add 100 agents at a time until more than 10 timeouts are encountered. For example, when testing the EC2 c5.2xlarge (8 cores and 16 GB), we start with 3,000 agents.

Cold-start versus warm-start scale testing

To simulate recovering from a Puppet Server restart, we use a cold-start scenario. We restart the `pe-puppetserver` service between each iteration so that the warm-up burden will reduce the maximum node count. This is the most conservative estimate of node capacity we test for.

To determine burst capacity, we use a warm-start scenario. When doing a warm-start scale test, we don’t restart the `pe-puppetserver` service, and we run the test on the same host that ran the cold-start tests to ensure it is already warmed up.

The extra capacity provided by a warmed up system is great for serving Puppet agent runs triggered by orchestration from the console, Continuous Delivery for Puppet Enterprise, or Bolt. Therefore we recommend keeping your node count near the cold-start numbers.

Soak testing

To ensure PE doesn’t suffer a performance degradation over time we run a soak test on each release. We use 600 agents, classified as large, checking in at the default 30-minute interval for 14 days. We run the warm-up before we start the test. This two-week test lets us verify that all garbage collection features are being triggered and keeping things under control. We check the Gatling response time graphs to ensure that performance is stable throughout the test.

Supported operating systems

Puppet Enterprise supports various operating systems depending on the role a machine assumes in your infrastructure.

Supported operating systems and devices

When choosing an operating system, first consider the machine’s role. Different roles support different operating systems and architectures.

Tip: For details about platform support lifecycles and planned end-of-life support, see Platform support lifecycle on the Puppet website.

Master platforms

The master role can be installed on these operating systems and architectures.

**SUSE Linux Enterprise Server dependencies**

When you install PE or an agent, these packages are also installed from the various operating system repositories.

If the machine you're installing on has internet access, most dependencies are installed during installation. If you encounter problems, inspect the error messages for packages that require other SUSE Linux Enterprise Server packaging modules to be enabled, and use `zypper package-search <PACKAGE NAME>` to locate them for manual installation.
### Ubuntu dependencies

When you install PE or an agent, these packages are also installed from the various operating system repositories.

If the machine you're installing on has internet access, dependencies are set up during installation. If your machine doesn't have internet access, you must manually install dependencies.

*For Ubuntu 18.04, use openjdk-8-jre-headless. This package requires the universe repository to install.

### AIX dependencies and limitations

Before installing the agent on AIX systems, install these packages.

- bash
- zlib
- readline
- curl
- openssl
CAUTION: For curl and openssl packages, you must use the versions provided by the "AIX Toolbox Cryptographic Content" repository, which is available via IBM support. Note that the cURL version must be 7.9.3. Do not use the cURL version in the AIX toolbox package for Linux applications, as that version does not support OpenSSL.

To install the bash, zlib, and readline packages on a node directly, run `rpm -Uvh` with the following URLs. The RPM package provider must be run as root.

- ftp://ftp.software.ibm.com/aix/freeSoftware/aixtoolbox/RPMS/ppc/readline/readline-4.3-2.aix5.1.ppc.rpm (AIX 5.3 only)

If you are behind a firewall or running an http proxy, the above commands might not work. Instead, use the AIX toolbox packages download available from IBM.

GPG verification does not work on AIX, because the RPM version it uses is too old. The AIX package provider doesn't support package downgrades (installing an older package over a newer package). Avoid using leading zeros when specifying a version number for the AIX provide, for example, use `2.3.4` not `02.03.04`.

The PE AIX implementation supports the NIM, BFF, and RPM package providers. Check the type reference for technical details on these providers.

Solaris dependencies and limitations

Solaris support is agent only.

For Solaris 10, these packages are required:
- SUNWgccruntime
- SUNWzlib
- In some instances, bash might not be present on Solaris systems. It needs to be installed before running the installer. Install bash via the media used to install the operating system, or via CSW if that is present on your system. (CSWbash or SUNWbash are both suitable.)

For Solaris 11 these packages are required:
- system/readline
- system/library/gcc-45-runtime
- library/security/openssl

These packages are available in the Solaris release repository, which is enabled by default in version 11. The installer automatically installs these packages; however, if the release repository is not enabled, the packages must be installed manually.

Upgrade your operating system with PE installed

If you have PE installed, take extra precautions before performing a major upgrade of your machine's operating system.

Performing major upgrades of your operating system with PE installed can cause errors and issues with PE. A major operating system upgrade is an upgrade to a new whole version, such as an upgrade from CentOS 6.0 to 7.0; it does not refer to a minor version upgrade, like CentOS 6.5 to 6.6. Major upgrades typically require a new version of PE.

1. Back up your databases and other PE files.
2. Perform a complete uninstall (using the `-p` and `-d` uninstaller options).
3. Upgrade your operating system.
4. Install PE.
5. Restore your backup.
Related information

Back up your infrastructure on page 647
PE backup creates a copy of your Puppet master, including configuration, certificates, code, and PuppetDB.

Restore your infrastructure on page 648
Use the restore commands to migrate your PE master to a new host or to recover from system failure.

Uninstalling on page 136
Puppet Enterprise includes a script for uninstalling. You can uninstall component infrastructure nodes or from agent nodes.

Installing Puppet Enterprise on page 95
Installing PE begins with setting up a standard installation: a master, console, and PuppetDB operating on a single node. From here, you can scale up to the large or extra-large installation as your infrastructure grows, or customize configuration as needed.

Supported browsers

The following browsers are supported for use with the console.

<table>
<thead>
<tr>

<tr>
<td>Apple Safari</td>
<td>10 or later</td>
</tr>
</tbody>
</table>

System configuration

Before installing Puppet Enterprise, make sure that your nodes and network are properly configured.

Note: Port numbers are Transmission Control Protocols (TCP), unless noted otherwise.

Timekeeping and name resolution

Before installing, there are network requirements you need to consider and prepare for. The most important requirements include syncing time and creating a plan for name resolution.

Timekeeping

Use NTP or an equivalent service to ensure that time is in sync between your master, which acts as the certificate authority, and any agent nodes. If time drifts out of sync in your infrastructure, you might encounter issues such as agents receiving outdated certificates. A service like NTP (available as a supported module) ensures accurate timekeeping.

Name resolution

Decide on a preferred name or set of names that agent nodes can use to contact the master. Ensure that the master can be reached by domain name lookup by all future agent nodes.

You can simplify configuration of agent nodes by using a CNAME record to make the master reachable at the hostname `puppet`, which is the default master hostname that is suggested when installing an agent node.

Web URLs used for deployment and management

PE uses some external web URLs for certain deployment and management tasks. You might want to ensure these URLs are reachable from your network prior to installation, and be aware that they might be called at various stages of configuration.

## What gets installed and where?

Puppet Enterprise installs several software components, configuration files, databases, services and users, and log files. It's useful to know the locations of these should you ever need to troubleshoot or manage your infrastructure.

### Software components installed

PE installs several software components and dependencies. These tables show which version of each component is installed for releases dating back to the previous long term supported (LTS) release.

The functional components of the software are separated between those packaged with the agent and those packaged on the server side (which also includes the agent).

**Note:** PE also installs other dependencies, as documented in the system requirements.

This table shows the components installed on all agent nodes.

**Note:** Hiera 5 is a backwards-compatible evolution of Hiera, which is built into Puppet 4.9.0 and higher. To provide some backwards-compatible features, it uses the classic Hiera 3.x.x codebase version listed in this table.

<table>

</tbody>
</table>
**Executable binaries and symlinks installed**

PE installs executable binaries and symlinks for interacting with tools and services.

On *nix nodes, all software is installed under `/opt/puppetlabs`.

On Windows nodes, all software is installed in Program Files at Puppet Labs\Puppet.

Executable binaries on *nix are in `/opt/puppetlabs/bin` and `/opt/puppetlabs/sbin`.

**Tip:** To include binaries in your default `$PATH`, manually add them to your profile or export the path:

```
export PATH=$PATH:/opt/puppetlabs/bin
```

To make essential Puppet tools available to all users, the installer automatically creates symlinks in `/usr/local/bin` for the `facter`, `puppet`, `pe-man`, `r10k`, and `hiera` binaries. Symlinks are created only if `/usr/local/bin` is writeable. Users of AIX and Solaris versions 10 and 11 must add `/usr/local/bin` to their default path.

For macOS agents, symlinks aren't created until the first successful run that applies the agents' catalogs.

**Tip:** You can disable symlinks by changing the `manage_symlinks` setting in your default Hiera file:

```
puppet_enterprise::manage_symlinks: false
```

Binaries provided by other software components, such as those for interacting with the PostgreSQL server, PuppetDB, or Ruby packages, do not have symlinks created.

**Modules and plugins installed**

PE installs modules and plugins for normal operations.

Modules included with the software are installed on the master in `/opt/puppetlabs/puppet/modules`. Don't modify anything in this directory or add modules of your own. Instead, install non-default modules in `/etc/puppetlabs/code/environments/<environment>/modules`.

**Configuration files installed**

PE installs configuration files that you might need to interact with from time to time.

On *nix nodes, configuration files live at `/etc/puppetlabs/puppet`.

On Windows nodes, configuration files live at `<COMMON_APPDATA>\PuppetLabs`. The location of this folder varies by Windows version; in 2008 and 2012, its default location is `\ProgramData\PuppetLabs\puppet \etc`.

The software's `confdir` is in the `puppet` subdirectory. This directory contains the `puppet.conf` file, `auth.conf`, and the SSL directory.

Tools installed

PE installs several suites of tools to help you work with the major components of the software.

- **Puppet tools** — Tools that control basic functions of the software such as puppet master and puppet cert.
- **Client tools** — The pe-client-tools package collects a set of CLI tools that extend the ability for you to access services from the master or a workstation. This package includes:
  - **Orchestrator** — The orchestrator is a set of interactive command line tools that provide the interface to the orchestration service. Orchestrator also enables you to enforce change on the environment level. Tools include puppet job and puppet app.
  - **Puppet Access** — Users can generate tokens to authenticate their access to certain command line tools and API endpoints.
  - **Code Manager CLI** — The puppet-code command allows you to trigger Code Manager from the command line to deploy your environments.
  - **PuppetDB CLI** — This a tool for working with PuppetDB, including building queries and handling exports.
- **Module tool** — The module tool is used to access and create modules, which are reusable chunks of Puppet code users have written to automate configuration and deployment tasks. For more information, and to access modules, visit the Forge.
- **Console** — The console is the web user interface for PE. The console provides tools to view and edit resources on your nodes, view reports and activity graphs, and more.

Databases installed

PE installs several default databases, all of which use PostgreSQL as a database backend.

The PE PostgreSQL database includes these following databases.

<table>
<thead>
<tr>
<th>Database</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-activity</td>
<td>Activity data from the classifier, including who, what, and when.</td>
</tr>
<tr>
<td>pe-classifier</td>
<td>Classification data, all node group information.</td>
</tr>
<tr>
<td>pe-puppetdb</td>
<td>PuppetDB data, including exported resources, catalogs, facts, and reports.</td>
</tr>
<tr>
<td>pe-rbac</td>
<td>RBAC data, including users, permissions, and AD/LDAP info.</td>
</tr>
<tr>
<td>pe-orchestrator</td>
<td>Orchestration data, including details about job runs.</td>
</tr>
</tbody>
</table>

Use the native PostgreSQL tools to perform database exports and imports. At a minimum, perform backups to a remote system nightly, or as dictated by your company policy.

Services installed

PE installs several services used to interact with the software during normal operations.

<table>
<thead>
<tr>
<th>Service</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-console-services</td>
<td>Manages and serves the console.</td>
</tr>
<tr>
<td>pe-puppetserver</td>
<td>Runs the master server, which manages the master component.</td>
</tr>
<tr>
<td>pe-nginx</td>
<td>Nginx, serves as a reverse-proxy to the console.</td>
</tr>
<tr>
<td>puppet</td>
<td>(on Enterprise Linux and Debian-based platforms) Runs the agent daemon on every agent node.</td>
</tr>
</tbody>
</table>
### Service Definition

<table>
<thead>
<tr>
<th>Service</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-puppetdb, pe-postgresql</td>
<td>Daemons that manage and serve the database components. The pe-postgresql service is created only if the software installs and manages PostgreSQL.</td>
</tr>
<tr>
<td>pxp-agent</td>
<td>Runs the Puppet Execution Protocol agent process.</td>
</tr>
<tr>
<td>pe-orchestration-services</td>
<td>Runs the orchestration process.</td>
</tr>
</tbody>
</table>

### User and group accounts installed

These are the user and group accounts installed.

<table>
<thead>
<tr>
<th>User</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-puppet</td>
<td>Runs the master processes spawned by pe-puppetserver.</td>
</tr>
<tr>
<td>pe-webserver</td>
<td>Runs Nginx.</td>
</tr>
<tr>
<td>pe-puppetdb</td>
<td>Has root access to the database.</td>
</tr>
<tr>
<td>pe-postgres</td>
<td>Has access to the pe-postgreSQL instance. Created only if the software installs and manages PostgreSQL.</td>
</tr>
<tr>
<td>pe-console-services</td>
<td>Runs the console process.</td>
</tr>
<tr>
<td>pe-orchestration-services</td>
<td>Runs the orchestration process.</td>
</tr>
</tbody>
</table>

### Log files installed

The software distributed with PE generates log files that you can collect for compliance or use for troubleshooting.

#### Master logs

The master has these logs.

- `/var/log/puppetlabs/puppetserver/code-manager-access.log`
- `/var/log/puppetlabs/puppetserver/file-sync-access.log`
- `/var/log/puppetserver/masterhttp.log`
- `/var/log/puppetserver/pcp-broker.log` — The log file for Puppet Communications Protocol brokers on compilers.
- `/var/log/puppetserver/puppetserver.log` — The master application logs its activity, including compilation errors and deprecation warnings, here.
- `/var/log/puppetserver/puppetserver-access.log`
- `/var/log/puppetserver/puppetserver-daemon.log` — This is where fatal errors or crash reports can be found.
- `/var/log/puppetserver/puppetserver-status.log`

#### Agent logs

The locations of agent logs depend on the agent operating system.

On *nix nodes, the agent service logs its activity to the syslog service. Your syslog configuration dictates where these messages are saved, but the default location is `/var/log/messages` on Linux, `/var/log/system.log` on macOS, and `/var/adm/messages` on Solaris.

On Windows nodes, the agent service logs its activity to the event log. You can view its logs by browsing the event viewer.
Console and console services logs

The console and pe-console-services has these logs.

- /var/log/puppetlabs/console-services/console-services.log
- /var/log/puppetlabs/console-services/console-services-api-access.log
- /var/log/puppetlabs/console-services-access.log
- /var/log/puppetlabs/console-services-daemon.log — This is where fatal errors or crash reports can be found.
- /var/log/puppetlabs/nginx/access.log
- /var/log/puppetlabs/nginx/error.log — Contains errors related to nginx. Console errors that aren’t logged elsewhere can be found in this log.

Installer logs

The installer has these logs.

- /var/log/puppetlabs/installer/http.log — Contains web requests sent to the installer. This log is present only on the machine from which a web-based installation was performed.
- /var/log/puppetlabs/installer/orchestrator_info.log — Contains run details about puppet infrastructure commands that use the orchestrator, including the commands to provision and upgrade compilers, convert legacy compilers, and regenerate agent and compiler certificates.
- /var/log/puppetlabs/installer/install_log.lastrun.<hostname>.log — Contains the contents of the last installer run.
- /var/log/puppetlabs/installer/installer-<timestamp>.log — Contains the operations performed and any errors that occurred during installation.
- /var/log/puppetlabs/installer/<action_name>_<timestamp>_<run_description>.log — Contains details about disaster recovery command execution. Each action triggers multiple Puppet runs, some on the master, some on the replica, so there might be multiple log files for each command.

Database logs

The database has these logs.

- /var/log/puppetlabs/postgresql/9.6/pgstartup.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Mon.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Tue.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Wed.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Thu.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Fri.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Sat.log
- /var/log/puppetlabs/postgresql/9.6/postgresql-Sun.log
- /var/log/puppetlabs/puppetdb/puppetdb.log
- /var/log/puppetlabs/puppetdb/puppetdb-access.log
- /var/log/puppetlabs/puppetdb/puppetdb-status.log

Orchestration logs

The orchestration service and related components have these logs.

- /var/log/puppetlabs/orchestration-services/aggregate-node-count.log
- /var/log/puppetlabs/orchestration-services/pcp-broker.log — The log file for Puppet Communications Protocol brokers on the master.
- /var/log/puppetlabs/orchestration-services/pcp-broker-access.log
- /var/log/puppetlabs/orchestration-services/orchestration-services.log
• /var/log/puppetlabs/orchestration-services/orchestration-services-access.log
• /var/log/puppetlabs/orchestration-services/orchestration-services-daemon.log — This is where fatal errors or crash reports can be found.
• /var/log/puppetlabs/orchestration-services/orchestration-services-status.log
• /var/log/puppetlabs/orchestration-services/orchestration-services.log — Log file for the node inventory service.

Certificates installed
During installation, the software generates and installs a number of SSL certificates so that agents and services can authenticate themselves.

These certs can be found at /etc/puppetlabs/puppet/ssl/certs.

A certificate with the same name as the agent that runs on the master is generated during installation. This certificate is used by PuppetDB and the console.

Services that run on the master — for example, pe-orchestration-services and pe-console-services — use the agent certificate to authenticate.

Secret key file installed
During installation, the software generates a secret key file that is used to encrypt and decrypt sensitive data stored in the inventory service.

The secret key is stored at: /etc/puppetlabs/orchestration-services/conf.d/secrets/keys.json

Installing Puppet Enterprise
Installing PE begins with setting up a standard installation: a master, console, and PuppetDB operating on a single node. From here, you can scale up to the large or extra-large installation as your infrastructure grows, or customize configuration as needed.

To install a FIPS-compliant PE master, install your master on a supported platform with FIPS mode enabled. The node must be configured with sufficient available entropy or the installation process fails.

Related information
Configuring disaster recovery on page 183
Enabling disaster recovery for Puppet Enterprise ensures that your systems can fail over to a replica of your master if infrastructure components become unreachable.

Installing compilers on page 125
As your Puppet Enterprise infrastructure scales up to 4,000 nodes and beyond, add load-balanced compilers to your installation to increase the number of agents you can manage.

Installing external PostgreSQL on page 133

© 2020 Puppet, Inc.
By default, Puppet Enterprise includes its own database backend, PE-PostgreSQL, which is installed alongside PuppetDB. If the load on your PuppetDB node is larger than it can effectively scale to (greater than 20,000 nodes), you can install a standalone instance of PE-PostgreSQL.

**Install PE**

Installation uses default settings to install all of the PE infrastructure components on a single node. After installing, you can scale or customize your installation as needed.

**Important:** Perform these steps on your target master node logged in as root. If you're installing on a system that doesn't enable root login, switch to the root user with this command: `sudo su -`

1. **Download** the tarball appropriate to your operating system and architecture.

   **Tip:** To download packages from the command line, run `wget --content-disposition <URL>` or `curl -JLO <URL>`, using the URL for the tarball you want to download.

2. **Unpack** the installation tarball:

   ```bash
tar -xf <TARBALL_FILENAME>
```

3. From the installer directory, run the installer:

   ```bash
./puppet-enterprise-installer
```

4. When prompted, specify a console administrator password: `puppet infrastructure console_password --password=<MY_PASSWORD>`

5. Run Puppet twice: `puppet agent -t`.

6. Optional: Restart the shell in order to use client tool commands.

**Verify the installation package**

If your organization requires that you verify authenticity before installing packages, follow these steps to verify the PE installation tarball using GPG.

**Before you begin**

You must have GnuPG installed to sign for the release key. GnuPG is an open source program that allows you to safely encrypt and sign digital communications. Visit the GnuPG website to download, or install using your package management system, for example `yum install gnupg`.

1. Import the Puppet public key.

   **Bash**

   ```bash
   uri='https://downloads.puppetlabs.com/puppet-gpg-signing-key.pub'
   curl "$uri" | gpg --import
   ```

2. Print the fingerprint of the key.

   ```bash
gpg --fingerprint 0x7F438280EF8D349F
```

The primary key fingerprint displays: 6F6B 1550 9CF8 E59E 6E46 9F32 7F43 8280 EF8D 349F.
3. Verify the release signature of the installation package.

   $ gpg --verify puppet-enterprise-<version>-<platform>.tar.gz.asc

   The result is similar to:

   gpg: Signature made Tue 18 Sep 2016 10:05:25 AM PDT using RSA key ID
   EF8D349F
gpg: Good signature from "Puppet, Inc. Release Key (Puppet, Inc. Release Key)"

   **Note:** If you don't have a trusted path to one of the signatures on the release key, you receive a warning that a valid path to the key couldn't be found.

### Configuration parameters and the `pe.conf` file

A `pe.conf` file is a HOCON formatted file that declares parameters and values used to install, upgrade, or configure PE. A default `pe.conf` file is available in the `conf.d` directory in the installer tarball.

**Tip:** You can install PE using a customized `pe.conf` file by running `./puppet-enterprise-installer -c <PATH_TO_pe.conf>`.

The following are examples of valid parameter and value expressions:

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FQDNs</td>
<td>&quot;puppet_enterprise::puppet_master_host&quot;: &quot;master.example.com&quot;</td>
</tr>
<tr>
<td>Strings</td>
<td>&quot;console_admin_password&quot;: &quot;mypassword&quot;</td>
</tr>
<tr>
<td>Arrays</td>
<td>[ &quot;puppet&quot;, &quot;puppetlb-01.example.com&quot; ]</td>
</tr>
<tr>
<td>Booleans</td>
<td>&quot;puppet_enterprise::profile::orchestrator::run_service&quot;: true</td>
</tr>
<tr>
<td></td>
<td>Valid Boolean values are true or false (case sensitive, no quotation marks).</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Don't use Yes (y), No (n), 1, or 0.</td>
</tr>
<tr>
<td>JSON hashes</td>
<td>&quot;puppet_enterprise::profile::orchestrator::java_args&quot;:</td>
</tr>
<tr>
<td></td>
<td>{ &quot;Xmx&quot;: &quot;256m&quot;, &quot;Xms&quot;: &quot;256m&quot; }</td>
</tr>
<tr>
<td>Integer</td>
<td>&quot;puppet_enterprise::profile::console::rbac_session_timeout&quot;: &quot;60&quot;</td>
</tr>
</tbody>
</table>

**Important:** Don't use single quotes on parameter values. Use double quotes as shown in the examples.

### Installation parameters

These parameters are required for installation.

**Tip:** To simplify installation, you can keep the default value of `%{::trusted.certname}` for your master and provide a console administrator password after running the installer.

**puppet_enterprise::puppet_master_host**

The FQDN of the node hosting the master, for example master.example.com.

Default: `%{::trusted.certname}`
**Database configuration parameters**

These are the default parameters and values supplied for the PE databases.

This list is intended for reference only; don't change or customize these parameters.

- **puppet_enterprise::activity_database_name**
  Name for the activity database.
  Default: `pe-activity`

- **puppet_enterprise::activity_database_read_user**
  Activity database user that can perform only read functions.
  Default: `pe-activity-read`

- **puppet_enterprise::activity_database_write_user**
  Activity database user that can perform only read and write functions.
  Default: `pe-activity-write`

- **puppet_enterprise::activity_database_super_user**
  Activity database superuser.
  Default: `pe-activity`

- **puppet_enterprise::activity_service_migration_db_user**
  Activity service database user used for migrations.
  Default: `pe-activity`

- **puppet_enterprise::activity_service_regular_db_user**
  Activity service database user used for normal operations.
  Default: `pe-activity-write`

- **puppet_enterprise::classifier_database_name**
  Name for the classifier database.
  Default: `pe-classifier`

- **puppet_enterprise::classifier_database_read_user**
  Classifier database user that can perform only read functions.
  Default: `pe-classifier-read`

- **puppet_enterprise::classifier_database_write_user**
  Classifier database user that can perform only read and write functions.
  Default: `pe-classifier-write`

- **puppet_enterprise::classifier_database_super_user**
  Classifier database superuser.
  Default: `pe-classifier`

- **puppet_enterprise::classifier_service_migration_db_user**
  Classifier service user used for migrations.
  Default: `pe-classifier`

- **puppet_enterprise::classifier_service_regular_db_user**
  Classifier service user used for normal operations.
  Default: `pe-classifier-write`

- **puppet_enterprise::orchestrator_database_name**
  Name for the orchestrator database.
Default: `pe-orchestrator`

**puppet_enterprise::orchestrator_database_read_user**
Orchestrator database user that can perform only read functions.
Default: `pe-orchestrator-read`

**puppet_enterprise::orchestrator_database_write_user**
Orchestrator database user that can perform only read and write functions.
Default: `pe-orchestrator-write`

**puppet_enterprise::orchestrator_database_super_user**
Orchestrator database superuser.
Default: `pe-orchestrator`

**puppet_enterprise::orchestrator_service_migration_db_user**
Orchestrator service user used for migrations.
Default: `pe-orchestrator`

**puppet_enterprise::orchestrator_service_regular_db_user**
Orchestrator service user used for normal operations.
Default: `pe-orchestrator-write`

**puppet_enterprise::puppetdb_database_name**
Name for the PuppetDB database.
Default: `pe-puppetdb`

**puppet_enterprise::rbac_database_name**
Name for the RBAC database.
Default: `pe-rbac`

**puppet_enterprise::rbac_database_read_user**
RBAC database user that can perform only read functions.
Default: `pe-rbac-read`

**puppet_enterprise::rbac_database_write_user**
RBAC database user that can perform only read and write functions.
Default: `pe-rbac-write`

**puppet_enterprise::rbac_database_super_user**
RBAC database superuser.
Default: `pe-rbac`

**puppet_enterprise::rbac_service_migration_db_user**
RBAC service user used for migrations.
Default: `pe-rbac`

**puppet_enterprise::rbac_service_regular_db_user**
RBAC service user used for normal operations.
Default: `pe-rbac-write`
External PostgreSQL parameters
These parameters are required to install an external PostgreSQL instance. Password parameters can be added to standard installations if needed.

**puppet_enterprise::database_host**
Agent certname of the node hosting the database component. Don't use an alt name for this value.

**puppet_enterprise::database_port**
The port that the database is running on.
Default: 5432

**puppet_enterprise::database_ssl**
true or false. For unmanaged PostgreSQL installations don't use SSL security, set this parameter to false.
Default: true

**puppet_enterprise::database_cert_auth**
true or false.

**Important**: For unmanaged PostgreSQL installations don't use SSL security, set this parameter to false.
Default: true

**puppet_enterprise::puppetdb_database_password**
Password for the PuppetDB database user. Must be a string, such as "mypassword".

**puppet_enterprise::classifier_database_password**
Password for the classifier database user. Must be a string, such as "mypassword".

**puppet_enterprise::classifier_service_regular_db_user**
Database user the classifier service uses for normal operations.
Default: pe-classifier

**puppet_enterprise::classifier_service_migration_db_user**
Database user the classifier service uses for migrations.
Default: pe-classifier

**puppet_enterprise::activity_database_password**
Password for the activity database user. Must be a string, such as "mypassword".

**puppet_enterprise::activity_service_regular_db_user**
Database user the activity service uses for normal operations.
Default: "pe-activity"

**puppet_enterprise::activity_service_migration_db_user**
Database user the activity service uses for migrations.
Default: "pe-activity"

**puppet_enterprise::rbac_database_password**
Password for the RBAC database user. Must be a string, such as "mypassword".

**puppet_enterprise::rbac_service_regular_db_user**
Database user the RBAC service uses for normal operations.
Default: "pe-rbac"

**puppet_enterprise::rbac_service_migration_db_user**
Database user the RBAC service uses for migrations.
Default: "pe-rbac"
**puppet_enterprise::orchestrator_database_password**
Password for the orchestrator database user. Must be a string, such as "mypassword".

**puppet_enterprise::orchestrator_service_regular_db_user**
Database user the orchestrator service uses for normal operations.
Default: pe-orchestrator

**puppet_enterprise::orchestrator_service_migration_db_user**
Database user the orchestrator service uses for migrations.
Default: "pe-orchestrator"

**Master parameters**
Use these parameters to configure and tune the master.

**pe_install::puppet_master_dnsaltnames**
An array of strings that represent the DNS altnames to be added to the SSL certificate generated for the master.
Default: ["puppet"]

**pe_install::install::classification::pe_node_group_environment**
String indicating the environment that infrastructure nodes are installed in. Specify this parameter if your master and other infrastructure nodes are installed in an environment other than production. With non-default infrastructure, this setting ensures that your configuration settings are backed up.
Default: ["production"]

**puppet_enterprise::profile::certificate_authority**
Array of additional certificates to be allowed access to the /certificate_status API endpoint. This list is added to the base certificate list.

**puppet_enterprise::profile::master::code_manager_auto_configure**
true to automatically configure the Code Manager service, or false.

**puppet_enterprise::profile::master::r10k_remote**
String that represents the Git URL to be passed to the r10k.yaml file, for example "git@your.git.server.com:puppet/control.git". The URL can be any URL that's supported by r10k and Git. This parameter is required only if you want r10k configured when PE is installed; it must be specified in conjunction with puppet_enterprise::profile::master::r10k_private_key.

**puppet_enterprise::profile::master::r10k_private_key**
String that represents the local file system path on the master where the SSH private key can be found and used by r10k, for example "/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa". This parameter is required only if you want r10k configured when PE is installed; it must be specified in conjunction with puppet_enterprise::profile::master::r10k_remote.

**puppet_enterprise::profile::master::check_for_updates**
true to check for updates whenever the pe-puppetserver service restarts, or false.
Default: true

**Console and console-services parameters**
Use these parameters to customize the behavior of the console and console-services. Parameters that begin with puppet_enterprise::profile can be modified from the console itself. See the configuration methods documents for more information on how to change parameters in the console or Hiera.

**puppet_enterprise::profile::console::classifier_synchronization_period**
Integer representing, in seconds, the classifier synchronization period, which controls how long it takes the node classifier to retrieve classes from the master.
Default: "600" (seconds).
**puppet-enterprise::profile::console::rbac_failed_attempts_lockout**  
Integer specifying how many failed login attempts are allowed on an account before that account is revoked.  
Default: "10" (attempts).

**puppet-enterprise::profile::console::rbac_password_reset_expiration**  
Integer representing, in hours, how long a user's generated token is valid for. An administrator generates this token for a user so that they can reset their password.  
Default: "24" (hours).

**puppet-enterprise::profile::console::rbac_session_timeout**  
Integer representing, in minutes, how long a user's session can last. The session length is the same for node classification, RBAC, and the console.  
Default: "60" (minutes).

**puppet-enterprise::profile::console::session_maximum_lifetime**  
Integer representing the maximum allowable period that a console session can be valid. To not expire before the maximum token lifetime, set to 0.  
Supported units are "s" (seconds), "m" (minutes), "h" (hours), "d" (days), "y" (years). Units are specified as a single letter following an integer, for example "1d" (1 day). If no units are specified, the integer is treated as seconds.

**puppet-enterprise::profile::console::console_ssl_listen_port**  
Integer representing the port that the console is available on.  
Default: [443]

**puppet-enterprise::profile::console::ssl_listen_address**  
Nginx listen address for the console.  
Default: "0.0.0.0"

**puppet-enterprise::profile::console::classifier_prune_threshold**  
Integer representing the number of days to wait before pruning the size of the classifier database. If you set the value to "0", the node classifier service is never pruned.

**puppet-enterprise::profile::console::classifier_node_check_in_storage**  
"true" to store an explanation of how nodes match each group they're classified into, or "false".  
Default: "false"

**puppet-enterprise::profile::console::display_local_time**  
"true" to display timestamps in local time, with hover text showing UTC time, or "false" to show timestamps in UTC time.  
Default: "false"

Modify these configuration parameters in Hiera or `pe.conf`, not the console:

**puppet-enterprise::api_port**  
SSL port that the node classifier is served on.  
Default: [4433]

**puppet-enterprise::console_services::no_longer_reporting_cutoff**  
Length of time, in seconds, before a node is considered unresponsive.  
Default: 3600 (seconds)

**console_admin_password**  
The password to log into the console, for example "myconsolepassword".  
Default: Specified during installation.
Orchestrator and orchestration services parameters
Use these parameters to configure and tune the orchestrator and orchestration services.

**puppet_enterprise::profile::agent::pxp_enabled**
true to enable the Puppet Execution Protocol service, which is required to use the orchestrator and run Puppet from the console, or false.
Default: true

**puppet_enterprise::profile::bolt_server::concurrency**
An integer that determines the maximum number of concurrent requests orchestrator can make to bolt-server.

⚠️ **CAUTION**: Do not set a concurrency limit that is higher than the bolt-server limit. This can cause timeouts that lead to failed task runs.

Default: The default value is set to the current value stored for bolt-server.

**puppet_enterprise::profile::orchestrator::global_concurrent_compiles**
Integer representing how many concurrent compile requests can be outstanding to the master, across all orchestrator jobs.
Default: "8" requests

**puppet_enterprise::profile::orchestrator::job_prune_threshold**
Integer representing the days after which job reports should be removed.
Default: "30" days

**puppet_enterprise::profile::orchestrator::pcp_timeout**
Integer representing the length of time, in seconds, before timeout when agents attempt to connect to the Puppet Communications Protocol broker in a Puppet run triggered by the orchestrator.
Default: "30" seconds

**puppet_enterprise::profile::orchestrator::run_service**
true to enable orchestration services, or false.
Default: true

**puppet_enterprise::profile::orchestrator::task_concurrency**
Integer representing the number of tasks that can run at the same time.
Default: "250" tasks

**puppet_enterprise::profile::orchestrator::use_application_services**
true to enable application management, or false.
Default: false

**puppet_enterprise::pxp_agent::ping_interval**
Integer representing the interval, in seconds, between agents' attempts to ping Puppet Communications Protocol brokers.
Default: "120" seconds

**puppet_enterprise::pxp_agent::pxplogfile**
String representing the path to the Puppet Execution Protocol agent log file. Change as needed.
Default: /var/log/puppetlabs/pxp-agent/pxp-agent.log (*nix) or C:/ProgramData/PuppetLabs/pxp-agent/var/log/pxp-agent.log (Windows)

Related information
Configuring Puppet orchestrator on page 431

© 2020 Puppet, Inc.
Once you've installed PE or the client tools package, there are a few tasks you need to do to prepare your PE infrastructure for orchestration services.

**PuppetDB parameters**
Use these parameters to configure and tune PuppetDB.

**puppet_enterprise::puppetdb::command_processing_threads**
Integer representing how many command processing threads PuppetDB uses to sort incoming data. Each thread can process a single command at a time.

Default: Half the number of cores in your system, for example "8".

**puppet_enterprise::profile::master::puppetdb_report_processor_ensure**
*present* to generate agent run reports and submit them to PuppetDB, or *absent*

Default: *present*

**puppet_enterprise::puppetdb_port**
Integer in brackets representing the SSL port that PuppetDB listens on.

Default: "[8081]"

**puppet_enterprise::profile::puppetdb::node_purge_ttl**
“Time-to-live” value before deactivated or expired nodes are deleted, along with all facts, catalogs, and reports for the node. For example, a value of "14d" sets the time-to-live to 14 days.

Default: "14d"

**Java parameters**
Use these parameters to configure and tune Java.

**puppet_enterprise::profile::master::java_args**
JVM (Java Virtual Machine) memory, specified as a JSON hash, that is allocated to the Puppet Server service, for example {"Xmx": "4096m", "Xms": "4096m"}.

**puppet_enterprise::profile::puppetdb::java_args**
JVM memory, specified as a JSON hash, that is allocated to the PuppetDB service, for example {"Xmx": "512m", "Xms": "512m"}.

**puppet_enterprise::profile::console::java_args**
JVM memory, specified as a JSON hash, that is allocated to console services, for example {"Xmx": "512m", "Xms": "512m"}.

**puppet_enterprise::profile::orchestrator::java_args**
JVM memory, set as a JSON hash, that is allocated to orchestration services, for example, {"Xmx": "256m", "Xms": "256m"}.

**Purchasing and installing a license key**
Your license must support the number of nodes that you want to manage with Puppet Enterprise.

**Complimentary license**
You can manage up to 10 nodes at no charge, and no license key is needed. When you have 11 or more active nodes and no license key, license warnings appear in the console until you install an appropriate license key.

**Purchased license**
To manage 11 or more active nodes, you must purchase a license. After you purchase a license and install a license key file, your licensed node count and subscription expiration date appear on the License page.
Note: To support spikes in node usage, four days per calendar month you can exceed your licensed node count up to double the number of nodes you purchased. This increased number of nodes is called your bursting limit. You must buy more nodes for your license if you exceed the licensed node count within the bursting limit on more than four days per calendar month, or if you exceed your bursting limit at all. In these cases, license warnings appear in the console until you contact your Puppet representative.

Related information
How nodes are counted on page 293

Your node count is the number of nodes in your inventory. Your license limits you to a certain number of active nodes before you hit your bursting limit. If you hit your bursting limit on four days during a month, you must purchase a license for more nodes or remove some nodes from your inventory.

Getting a license

Contact Puppet to purchase a license subscription.

- New PE customers — Purchase a subscription from the Puppet website, or contact our sales team. Find more information at Ready to buy Puppet Enterprise?
- Existing PE customers — To add nodes, upgrade, or renew your annual license, contact your sales representative or email sales@puppet.com.

Tip: To reduce your active node count and free up licenses, remove inactive nodes from your deployment. By default, nodes with Puppet agents are automatically deactivated after seven days with no activity (no new facts, catalog, or reports).

Related information
Remove agent nodes on page 289

If you no longer wish to manage an agent node, you can remove it and make its license available for another node.

Install a license key

Install the license.key file to upgrade from a test installation to an active installation.

1. Install the license key by copying the file to /etc/puppetlabs/license.key on the master node.
2. Verify that Puppet has permission to read the license key by checking its ownership and permissions: ls -la /etc/puppetlabs/license.key
3. If the ownership is not root and permissions are not -rw-r--r-- (octal 644), set them:

   sudo chown root:root /etc/puppetlabs/license.key
   sudo chmod 644 /etc/puppetlabs/license.key

View license details for your environment

Check the number of active nodes in your deployment, the number of licensed nodes you purchased, and the expiration date for your license.

Procedure

- In the console, click License.

The License page opens with information on your licensed nodes, bursting limit, and subscription expiration date. Any license warnings that appear in the console navigation are explained here. For example, if your license is expired or out of compliance.

Related information
Remove agent nodes on page 289

If you no longer wish to manage an agent node, you can remove it and make its license available for another node.

Puppet orchestrator API: usage endpoint on page 570

© 2020 Puppet, Inc.
Use the /usage endpoint to view details about the active nodes in your deployment.

## Installing agents

You can install Puppet Enterprise agents on *nix, Windows, and macOS.

To install FIPS-compliant PE agents, install the agent on a supported platform with FIPS mode enabled.

Agents are typically installed from a package repository hosted on your master. The PE package management repository is created during installation of the master and serves packages over HTTPS using the same port as the master (8140). This means agents don't require any new ports to be open other than the one they already need to communicate with the master.

Agent packages can be found on the master in `/opt/puppetlabs/server/data/packages/public/ <PE VERSION>/`. This directory contains the platform specific repository file structure for agent packages. For example, if your master is running on CentOS 7, in `/opt/puppetlabs/server/data/packages/public/ <PE VERSION>/`, there's a directory `el-7-x86_64`, which contains the directories with all the packages needed to install an agent.

After installing agents, you must sign their certificates.

### Using the install script

The install script installs and configures the agent on target nodes using installation packages from the PE package management repo.

The agent install script performs these actions:

- Detects the operating system on which it's running, sets up an apt, yum, or zipper repo that refers back to the master, and then pulls down and installs the `puppet-agent` packages. If the install script can't find agent packages corresponding to the agent's platform, it fails with an error telling you which `pe_repo` class you need to add to the master.
- Downloads a tarball of plugins from the master. This feature is controlled by the settings `pe_repo::enable_bulk_pluginsync` and `pe_repo::enable_windows_bulk_pluginsync`, which is set to `true` (enabled) by default. Depending on how many modules you have installed, bulk plug-in sync can speed agent installation significantly.
  
  **Note:** If your master runs in a different environment from your agent nodes, you might see some reduced benefit from bulk plug-in sync. The plug-in tarball is created based on the plug-ins running on the master agent, which might not match the plug-ins required for agents in a different environment.

- Creates a basic `puppet.conf` file.
- Kicks off a Puppet run.

Automatic downloading of agent installer packages and plugins using the `pe_repo` class requires an internet connection.

**Tip:** If your master uses a proxy server to access the internet, prior to installation, specify `pe_repo::http_proxy_host` and `pe_repo::http_proxy_port` in `pe.conf`, Hiera, or in the console, in the `pe_repo` class of the PE Master node group.

© 2020 Puppet, Inc.
You can customize agent installation by providing as flags to the script any number of these options, in any order:

<table>
<thead>
<tr>
<th>Option</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
</table>
| puppet.conf settings        | agent:splay=true
agent:certname=node1.corp.net
agent:environment=development |
|                            | The puppet.conf file looks like this: [agent]
certname = node1.corp.net
splay = true
environment = development |

| CSR attribute settings     | extension_requests:pp_role=webserver
custom_attributes:challengePassword=abc123 |
|                            | The installer creates a csr_attributes.yaml file before installing with this content: ---
custom_attributes:
  challengePassword: abc123
extension_requests:
  pp_role: webserver |

| MSI properties (Windows only) | PuppetAgentAccountUser 'pup_adm'
PuppetAgentAccountPassword 'secret' |
|                              | The Puppet service runs as pup_adm with a password of secret. |

| Puppet service status       | *nix:
--puppet-service-ensure
stopped
--puppet-service-enable
false |
|                            | The Puppet service is stopped and doesn't boot after installation. An initial Puppet run doesn't occur after installation. |

|                            | Windows
-PuppetServiceEnsure
stopped
-PuppetServiceEnable
false |

**puppet.conf settings**

You can specify any agent configuration option using the install script. Configuration settings are added to puppet.conf.

These are the most commonly specified agent config options:

- server
- certname
- environment
- splay
- splaylimit
Tip: On Enterprise Linux systems, if you have a proxy between the agent and the master, you can specify `http_proxy_host`, for example `-s agent:http_proxy_host=<PROXY_FQDN>`. See the Configuration Reference for details.

**CSR attribute settings**

These settings are added to `puppet.conf` and included in the `custom_attributes` and `extension_requests` sections of `csr_attributes.yaml`.

You can pass as many parameters as needed. Follow the `section:key=value` pattern and leave one space between parameters.

See the `csr_attributes.yaml` reference for details.

*nix install script with example agent setup and certificate signing parameters:

**Bash**

```
uri='https://master.example.com:8140/packages/current/install.bash'

curl --insecure "$uri" | sudo bash -s agent:certname=<CERTNAME OTHER THAN FQDN> custom_attributes:challengePassword=<PASSWORD_FOR_AUTOSIGNER_SCRIPT> extension_requests:pp_role=<PUPPET NODE ROLE>
```

Windows install script with example agent setup and certificate signing parameters:

```
\install.ps1 agent:certname=<certnameOtherThanFQDN> custom_attributes:challengePassword=<passwordForAutosignerScript> extension_requests:pp_role=<puppetNodeRole>
```

**MSI properties (Windows)**

For Windows, you can set these MSI properties, with or without additional agent configuration settings.

<table>
<thead>
<tr>
<th>MSI Property</th>
<th>PowerShell flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSTALLDIR</td>
<td>-InstallDir</td>
</tr>
<tr>
<td>PUPPET_AGENT_ACCOUNT_USER</td>
<td>-PuppetAgentAccountUser</td>
</tr>
<tr>
<td>PUPPET_AGENT_ACCOUNT_PASSWORD</td>
<td>-PuppetAgentAccountPassword</td>
</tr>
<tr>
<td>PUPPET_AGENT_ACCOUNT_DOMAIN</td>
<td>-PuppetAgentAccountDomain</td>
</tr>
</tbody>
</table>

Windows install script with MSI properties and agent configuration settings:

```
$webClient.DownloadFile('https://<MASTER HOSTNAME>:8140/packages/current/install.ps1', 'install.ps1'); .\install.ps1 -PuppetAgentAccountUser "svcPuppet" -PuppetAgentAccountPassword "s3kr3t_P@ssword" agent:splay=true agent:environment=development
```
Puppet service status

By default, the install script starts the Puppet agent service and kicks off a Puppet run. If you want to manually trigger a Puppet run, or you're using a provisioning system that requires non-default behavior, you can control whether the service is running and enabled.

<table>
<thead>
<tr>
<th>Option</th>
<th>*nix</th>
<th>Windows</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>ensure</td>
<td>--puppet-service-ensure &lt;VALUE&gt;</td>
<td>PuppetServiceEnsure &lt;VALUE&gt;</td>
<td>running, stopped</td>
</tr>
<tr>
<td>enable</td>
<td>--puppet-service-enable &lt;VALUE&gt;</td>
<td>PuppetServiceEnable &lt;VALUE&gt;</td>
<td>true, false, manual (Windows only), mask</td>
</tr>
</tbody>
</table>

For example:

*nix

Bash

```bash
uri='https://<MASTER_FQDN>:8140/packages/current/install.bash'
curl --insecure "$uri" | sudo bash -s -- --puppet-service-ensure stopped
```

Windows

```
$webClient.DownloadFile('https://<PUPPET MASTER FQDN>:8140/packages/current/install.ps1', 'install.ps1'); .\install.ps1 -PuppetServiceEnsure stopped
```

Install *nix agents

You have multiple options for installing *nix agents: from the console, from the command line using PE package management or your own package management, with or without internet access, and more. Chose the installation method that best suits your needs.

Note:

You must enable TLSv1 to install agents on these platforms:

- AIX
- CentOS 5
- RHEL 5
- SLES 11
- Solaris 10
- Windows Server 2008r2

Related information

Enable TLSv1 on page 646
TLSv1 and TLSv1.1 are disabled by default in PE.

**Install agents from the console**
You can use the console to leverage tasks that install *nix or Windows agents on target nodes.

**Before you begin**
Add classes to the PE Master node group for each agent platform used in your environment. For example, `pe_repo::platform::el_7_x86_64`.

Make sure you have permission to run the appropriate task to install agents on all nodes:
- *nix targets use the task `pe_bootstrap::linux`
- Windows targets use the task `pe_bootstrap::windows`

For Windows targets, this task requires:
- Windows 2008 SP2 or newer
- PowerShell version 3 or higher
- Microsoft .NET Framework 4.5 or higher

1. In the console, on the **Nodes** page, click **Add nodes**.
2. Click **Install agents**.
3. Select a transport method.
   - **SSH** for *nix targets
   - **WinRM** for Windows targets
4. Enter the target host names and the credentials required to access them. If you use an SSH key, include begin and end tags.
5. Click **Add nodes**.

   **Tip:** Click **Installation job started** to view the job details for the task.

   Agents are installed on the target nodes and then automatically submit certificate signing requests (CSR) to the master. The list of unsigned certificates is updated with new targets.

**Related information**
- [Managing certificate signing requests in the console](#) on page 55
- A certificate signing request appears in the console on the **Unsigned certs** page after you add an agent node to inventory. Accept or reject submitted requests individually or in a batch.
- [Managing certificate signing requests on the command line](#) on page 124
- You can view, approve, and reject node requests using the command line.

**Install *nix agents with PE package management**
PE provides its own package management to help you install agents in your infrastructure.

**Note:** The `<MASTER HOSTNAME>` portion of the installer script—as provided in the following example—refers to the FQDN of the master. The FQDN must be fully resolvable by the machine on which you're installing or upgrading the agent.
1. If you're installing an agent with a different OS than the master, add the appropriate class for the repo that contains the agent packages.
   a) In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Master** group.
   b) On the **Classes** tab, enter `pe_repo` and select the repo class from the list of classes.
   
   **Note:** The repo classes are listed as `pe_repo::platform::<AGENT_OS_VERSION_ARCHITECTURE>`.
   c) Click **Add class**, and commit changes.
   d) Run `puppet agent -t` to configure the master node using the newly assigned class.
   
   The new repo is created in `/opt/puppetlabs/server/data/packages/public/<PE VERSION>/<PLATFORM>/`.

2. SSH into the node where you want to install the agent, and run the installation command appropriate to your environment.
   • **Curl**
     
     **Bash**
     ```sh
     uri='https://<MASTER_HOSTNAME>:8140/packages/current/install.bash'
     curl --insecure "$uri" | sudo bash
     ```
     **Tip:** On AIX versions 7.10 and earlier, which don't support the `-k` option, use `--tlsv1` instead. If neither `-k` or `--tlsv1` is supported, you must install using a manually transferred certificate.
   • **RHEL 5 and CentOS 5**
     
     **Bash**
     ```sh
     uri='https://<MASTER_HOSTNAME>:8140/packages/current/install.bash'
     curl --insecure --tlsv1 "$uri" | sudo bash
     ```
   • **wget**
     ```sh
     wget -O - -q --no-check-certificate https://<MASTER HOSTNAME>:8140/packages/current/install.bash | sudo bash
     ```
   • **Solaris 10** (run as root)
     ```sh
     export PATH=$PATH:/opt/sfw/bin
     wget -O - -q --no-check-certificate --secure-protocol=TLSv1 https://<MASTER HOSTNAME>:8140/packages/current/install.bash | bash
     ```

**Install *nix agents with your own package management**

If you choose not to use PE package management to install agents, you can use your own package management tools.

**Before you begin**

**Download** the appropriate agent tarball.

1. Add the agent package to your own package management and distribution system.
2. Configure the package manager on your agent node (Yum, Apt) to point to that repo.
3. Install the agent using the command appropriate to your environment.
   - Yum
     
     ```
     sudo yum install puppet-agent
     ```
   - Apt
     
     ```
     sudo apt-get install puppet-agent
     ```

4. Configure the agent as needed: `puppet config set`

### Install *nix agents using a manually transferred certificate

If you choose not to or can't use `curl --insecure` to trust the master during agent installation, you can manually transfer the master CA certificate to any machines you want to install agents on, and then run the installation script against that cert.

1. On the machine that you're installing the agent on, create the directory `/etc/puppetlabs/puppet/ssl/certs`.
2. On the master, navigate to `/etc/puppetlabs/puppet/ssl/certs/` and transfer `ca.pem` to the `certs` directory you created on the agent node.
3. On the agent node, verify file permissions: `chmod 444 /etc/puppetlabs/puppet/ssl/certs/ca.pem`
4. Run the installation command, using the `--cacert` flag to point to the cert:

   **Bash**

   ```
   cacert='/etc/puppetlabs/puppet/ssl/certs/ca.pem'
   uri='https://<MASTER HOSTNAME>:8140/packages/current/install.bash'
   curl --cacert "$cacert" "$uri" | sudo bash
   ```

### Install *nix agents without internet access

If you don't have access to the internet beyond your infrastructure, you can download the appropriate agent tarball from an internet-connected system and then install using the package management solution of your choice.

### Install *nix agents with PE package management without internet access

Use PE package management to install agents when you don't have internet access beyond your infrastructure.

#### Before you begin

**Download** the appropriate agent tarball.

1. On your master, copy the agent tarball to `/opt/puppetlabs/server/data/staging/pe_repo-puppet-agent--<AGENT_VERSION>`, for example `/opt/puppetlabs/server/data/staging/pe_repo-puppet-agent-5.5.17/`
2. If you're installing an agent with a different OS than the master, add the appropriate class for the repo that contains the agent packages.
   a) In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Master** group.
   b) On the **Classes** tab, enter `pe_repo` and select the repo class from the list of classes.
      
      **Note:** The repo classes are listed as `pe_repo::platform::<AGENT_OS_VERSION_ARCHITECTURE>`.
   c) Click **Add class**, and commit changes.
3. Run Puppet: `puppet agent -t`
4. Follow the steps for **Install *nix agents with PE package management** on page 110.
Install *nix agents with your own package management without internet access

Use your own package management to install agents when you don’t have internet access beyond your infrastructure.

Before you begin

Download the appropriate agent tarball.

1. Add the agent package to your own package management and distribution system.
2. Disable the PE-hosted repo.
   a) In the console, click Node groups, and in the PE Infrastructure group, select the PE Master group.
   b) On the Classes tab, find pe_repo class (as well as any class that begins pe_repo::), and click Remove this class.
   c) Commit changes.

Install *nix agents from compilers using your own package management without internet access

If your infrastructure relies on compilers to install agents, you don’t have to copy the agent package to each compiler. Instead, use the console to specify a path to the agent package on your package management server.

Before you begin

Download the appropriate agent tarball.

1. Add the agent package to your own package management and distribution system.
2. Set the base_path parameter of the pe_repo class to your package management server.
   a) In the console, click Node groups, and in the PE Infrastructure group, select the PE Master group.
   b) On the Classes tab, find the pe_repo class and specify the parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_path</td>
<td>FQDN of your package management server.</td>
</tr>
</tbody>
</table>
   c) Click Add parameter and commit changes.

Install Windows agents

You have multiple options for installing Windows agents: from the console, from a PowerShell window using PE package management, from the command line using an .msi package, and more. Chose the installation method that best suits your needs.

Note:

You must enable TLSv1 to install agents on these platforms:

- AIX
- CentOS 5
- RHEL 5
- SLES 11
- Solaris 10
- Windows Server 2008r2

Related information

Enable TLSv1 on page 646
TLSv1 and TLSv1.1 are disabled by default in PE.

**Install agents from the console**

You can use the console to leverage tasks that install *nix or Windows agents on target nodes.

**Before you begin**

Add classes to the **PE Master** node group for each agent platform used in your environment. For example, `pe_repo::platform::el_7_x86_64`.

Make sure you have permission to run the appropriate task to install agents on all nodes:

- *nix targets use the task `pe_bootstrap::linux`
- Windows targets use the task `pe_bootstrap::windows`

For Windows targets, this task requires:

- Windows 2008 SP2 or newer
- PowerShell version 3 or higher
- Microsoft .NET Framework 4.5 or higher

1. In the console, on the **Nodes** page, click **Add nodes**.
2. Click **Install agents**.
3. Select a transport method.
   - **SSH** for *nix targets
   - **WinRM** for Windows targets
4. Enter the target host names and the credentials required to access them. If you use an SSH key, include begin and end tags.
5. Click **Add nodes**.

**Tip:** Click **Installation job started** to view the job details for the task.

Agents are installed on the target nodes and then automatically submit certificate signing requests (CSR) to the master. The list of unsigned certificates is updated with new targets.

**Related information**

* Managing certificate signing requests in the console on page 55

A certificate signing request appears in the console on the **Unsigned certs** page after you add an agent node to inventory. Accept or reject submitted requests individually or in a batch.

* Managing certificate signing requests on the command line on page 124

You can view, approve, and reject node requests using the command line.

**Install Windows agents with PE package management**

To install a Windows agent with PE package management, you use the `pe_repo` class to distribute an installation package to agents. You can use this method with or without internet access.

**Before you begin**

If your master doesn't have internet access, download the appropriate agent package and save it on your master in the location appropriate for your agent systems:

- **32-bit systems** — /opt/puppetlabs/server/data/packages/public/<PE_VERSION>/windows-i386-<AGENT_VERSION>/
- **64-bit systems** — /opt/puppetlabs/server/data/packages/public/<PE_VERSION>/windows-x86_64-<AGENT_VERSION>/

You must use PowerShell 2.0 or later to install Windows agents with PE package management.

© 2020 Puppet, Inc.
Note: The `<MASTER HOSTNAME>` portion of the installer script—as provided in the following example—refers to the FQDN of the master. The FQDN must be fully resolvable by the machine on which you're installing or upgrading the agent.

1. In the console, click Node groups, and in the PE Infrastructure group, select the PE Master group.
2. On the Classes tab, type pe_repo and select the appropriate repo class from the list of classes.
   - 64-bit (x86_64) — `pe_repo::platform::windows_x86_64`.
   - 32-bit (i386) — `pe_repo::platform::windows_i386`.
3. Click Add class and commit changes.
4. On the master, run Puppet to configure the newly assigned class.
   
   The new repository is created on the master at `/opt/puppetlabs/server/data/packages/public/<PE VERSION>/<PLATFORM>/`.
5. On the node, open an administrative PowerShell window, and install:

   ```bash
   [System.Net.ServicePointManager]::ServerCertificateValidationCallback = {$true};
   $webClient.DownloadFile('https://<MASTER_HOST>:8140/packages/current/install.ps1', 'install.ps1'); .\install.ps1 -v
   ``

   Microsoft Windows Server 2008r2 only:

   ```bash
   [System.Net.ServicePointManager]::ServerCertificateValidationCallback = {$true};
   $webClient.DownloadFile('https://<MASTER_HOST>:8140/packages/current/install.ps1', 'install.ps1'); .\install.ps1 -v
   ```

   After running the installer, you see the following output, which indicates the agent was successfully installed.

   ```bash
   Notice: /Service[puppet]/ensure: ensure changed 'stopped' to 'running' service {'puppet':
   ensure => 'running',
   enable => 'true',
   }
   ```

   **Install Windows agents using a manually transferred certificate**

   If you need to perform a secure installation on Windows nodes, you can manually transfer the master CA certificate to target nodes, and run a specialized installation script against that cert.

   1. Transfer the installation script and the CA certificate from your master to the node you're installing.

<table>
<thead>
<tr>
<th>File</th>
<th>Location on master</th>
<th>Location on target node</th>
</tr>
</thead>
<tbody>
<tr>
<td>Installation script (install.ps1)</td>
<td>/opt/puppetlabs/server/data/packages/public/</td>
<td>Any accessible local directory.</td>
</tr>
<tr>
<td>CA certificate (ca.pem)</td>
<td>/etc/puppetlabs/puppet/ssl/certs/</td>
<td>C:\ProgramData\PuppetLabs\puppet\etc \ssl\certs\</td>
</tr>
</tbody>
</table>

   2. Run the installation script, using the `-UsePuppetCA` flag: `.\install.ps1 -UsePuppetCA`
Install Windows agents with the .msi package
Use the Windows .msi package if you need to specify agent configuration details during installation, or if you need to install Windows agents locally without internet access.

Before you begin
Download the .msi package.

Tip: To install on nodes that don't have internet access, save the .msi package to the appropriate location for your system:

- 32-bit systems — /opt/puppetlabs/server/data/packages/public/<PE_VERSION>/windows-i386-<AGENT_VERSION>/
- 64-bit systems — /opt/puppetlabs/server/data/packages/public/<PE_VERSION>/windows-x86_64-<AGENT_VERSION>/

Install Windows agents with the installer
Use the MSI installer for a more automated installation process. The installer can configure puppet.conf, create CSR attributes, and configure the agent to talk to your master.

1. Run the installer as administrator.
2. When prompted, provide the hostname of your master, for example puppet.

Install Windows agents using msiexec from the command line
Install the MSI manually from the command line if you need to customize puppet.conf, CSR attributes, or certain agent properties.

On the command line of the node that you want to install the agent on, run the install command:

msiexec /qn /norestart /i <PACKAGE_NAME>.msi

Tip: You can specify /l*v install.txt to log the progress of the installation to a file.

MSI properties
If you install Windows agents from the command line using the .msi package, you can optionally specify these properties.

Important: If you set a non-default value for PUPPET_MASTER_SERVER, PUPPET_CA_SERVER, PUPPET_AGENT_CERTNAME, or PUPPET_AGENT_ENVIRONMENT, the installer replaces the existing value in puppet.conf and re-uses the value at upgrade unless you specify a new value. Therefore, if you've customized these properties, don't change the setting directly in puppet.conf; instead, re-run the installer and set a new value at installation.

</table>
To install the agent to a domain user ExampleCorp\bob:

```cmd
msiexec /qn /norestart /i puppet-<VERSION>.msi
PUPPET_AGENT_ACCOUNT_DOMAIN=ExampleCorp PUPPET_AGENT_ACCOUNT_USER=bob
PUPPET_AGENT_ACCOUNT_PASSWORD=password
```

**Windows agent installation details**

Windows nodes can fetch configurations from a master and apply manifests locally, and respond to orchestration commands.

After installing a Windows node, the **Start Menu** contains a **Puppet** folder with shortcuts for running the agent manually, running Facter, and opening a command prompt for use with Puppet tools.

**Note:** You must run Puppet with elevated privileges. Select **Run as administrator** when opening the command prompt.

The agent runs as a Windows service. By default, the agent fetches and applies configurations every 30 minutes. The agent service can be started and stopped independently using either the service control manager UI or the command line `sc.exe` utility.

Puppet is automatically added to the machine's `PATH` environment variable, so you can open any command line and run `puppet`, `facter` and the other batch files that are in the `bin` directory of the Puppet installation. Items necessary for the Puppet environment are also added to the shell, but only for the duration of execution of each of the particular commands.

The installer includes Ruby, gems, and Facter. If you have existing copies of these applications, such as Ruby, they aren't affected by the re-distributed version included with Puppet.

**Program directory**

Unless overridden during installation, PE and its dependencies are installed in **Program Files** at `\PuppetLabs\Puppet`.

You can locate the **Program Files** directory using the `PROGRAMFILES` variable or the `PROGRAMFILES(X86)` variable.

The program directory contains these subdirectories:

<table>
<thead>
<tr>
<th>Subdirectory</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>scripts for running Puppet and Facter</td>
</tr>
<tr>
<td>facter</td>
<td>Facter source</td>
</tr>
<tr>
<td>hiera</td>
<td>Hiera source</td>
</tr>
<tr>
<td>misc</td>
<td>resources</td>
</tr>
<tr>
<td>puppet</td>
<td>Puppet source</td>
</tr>
<tr>
<td>service</td>
<td>code to run the agent as a service</td>
</tr>
<tr>
<td>sys</td>
<td>Ruby and other tools</td>
</tr>
</tbody>
</table>

**Data directory**

PE stores settings, manifests, and generated data — such as logs and catalogs — in the data directory. The data directory contains two subdirectories for the various components:

- **`etc`** (the `$confdir`): Contains configuration files, manifests, certificates, and other important files.
- **`var`** (the `$vardir`): Contains generated data and logs.

© 2020 Puppet, Inc.
When you run Puppet with elevated privileges as intended, the data directory is located in the
COMMON_APPDATA.aspx folder. This folder is typically located at C:\ProgramData\PuppetLabs\.
Because the common app data directory is a system folder, it is hidden by default.

If you run Puppet without elevated privileges, it uses a .puppet directory in the current user's home folder as its
data directory, which can result in unexpected settings.

Install macOS agents
You can install macOS agents with PE package management, from Finder, or from the command line.
To install macOS agents with PE package management, follow the steps to Install *nix agents with PE package
management on page 110.

Important: For macOS agents, the certname is derived from the name of the machine (such as My-Example-Mac).
To prevent installation issues, make sure the name of the node uses lowercases letters. If you don’t want to change
your computer’s name, you can enter the agent certname in all lowercase letters when prompted by the installer.

Install macOS agents from Finder
You can use Finder to install the agent on your macOS machine.

Before you begin
Download the appropriate agent tarball.
1. Open the agent package .dmg and click the installer .pkg.
2. Follow prompts in the installer dialog.
   You must include the master hostname and the agent certname.

Install macOS agents from the command line
You can use the command line to install the agent on a macOS machine.

Before you begin
Download the appropriate agent tarball.
1. SSH into the node as a root or sudo user.
2. Mount the disk image: sudo hdiutil mount <DMGFILE>
   A line appears ending with /Volumes/puppet-agent-VERSION. This directory location is the mount point
   for the virtual volume created from the disk image.
3. Change to the directory indicated as the mount point in the previous step, for example: cd /Volumes/
puppet-agent-VERSION
4. Install the agent package: sudo installer -pkg puppet-agent-installer.pkg -target /
5. Verify the installation: /opt/puppetlabs/bin/puppet --version
6. Configure the agent to connect to the master: /opt/puppetlabs/bin/puppet config set server
   <MASTER_HOSTNAME>
7. Configure the agent certname: /opt/puppetlabs/bin/puppet config set certname
   <AGENT_CERTNAME>

macOS agent installation details
macOS agents include core Puppet functionality, plus platform-specific capabilities like package installation, service
management with LaunchD, facts inventory with the System Profiler, and directory services integration.

Install non-root agents
Running agents without root privileges can assist teams using PE to work autonomously.
For example, your infrastructure’s platform might be maintained by one team with root privileges while your
infrastructure’s applications are managed by a separate team (or teams) with diminished privileges. If the application
team wants to be able to manage its part of the infrastructure independently, they can run Puppet without root privileges.

PE is installed with root privileges, so you need a root user to install and configure non-root access to a master. The root user who performs this installation can then set up non-root users on the master and any nodes running an agent.

Non-root users can perform a reduced set of management tasks, including configuring settings, configuring Facter external facts, running `puppet agent --test`, and running Puppet with non-privileged cron jobs or a similar scheduling service. Non-root users can also classify nodes by writing or editing manifests in the directories where they have write privileges.

**Install non-root *nix agents**

**Note:** Unless specified otherwise, perform these steps as a root user.

1. Install the agent on each node that you want to operate as a non-root user.
2. Log in to the agent node and add the non-root user:

   ```bash
   puppet resource user <UNIQUE NON-ROOT USERNAME> ensure=present managehome=true
   
   Note: Each non-root user must have a unique name.
   ```

3. Set the non-root user password.

   For example, on most *nix systems: `passwd <USERNAME>`

4. Stop the `puppet` service:

   ```bash
   puppet resource service puppet ensure=stopped enable=false
   
   By default, the `puppet` service runs automatically as a root user, so it must be disabled.
   ```

5. Disable the Puppet Execution Protocol agent.

   a) In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Agent** group.

   b) On the **Classes** tab, select the **puppetenterprise::profile::agent** class, specify parameters, click **Add parameter**, and then commit changes.

   ![Parameter Value Table]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>pxp_enabled</td>
<td>false</td>
</tr>
</tbody>
</table>

6. Change to the non-root user and generate a certificate signing request:

   ```bash
   puppet agent -t --certname "<UNIQUE NON-ROOT USERNAME.HOSTNAME>" --server "<MASTER HOSTNAME>"
   
   Tip: If you wish to use `su - <NON-ROOT USERNAME>` to switch between accounts, make sure to use the `--` (−1 in some unix variants) argument so that full login privileges are correctly granted. Otherwise you might see permission denied errors when trying to apply a catalog.
   
7. On the master or in the console, approve the certificate signing request.
8. On the agent node as the non-root user, set the node’s certname and the master hostname, and then run Puppet.

```
puppet config set certname <UNIQUE NON-ROOT USERNAME.HOSTNAME> --section agent
```

```
puppet config set server <PUPPET MASTER HOSTNAME> --section agent
```

```
puppet agent -t
```

The configuration specified in the catalog is applied to the node.

**Tip:** If you see Facter facts being created in the non-root user’s home directory, you have successfully created a functional non-root agent.

To confirm that the non-root agent is correctly configured, verify that:

- The agent can request certificates and apply the catalog from the master when a non-root user runs Puppet:
  
  ```
  puppet agent -t
  ```

- The agent service is not running:
  
  ```
  service puppet status
  ```

- Non-root users can collect existing facts by running `facter` on the agent, and they can define new, external facts.

### Install non-root Windows agents

**Note:** Unless specified otherwise, perform these steps as a root user.

1. Install the agent on each node that you want to operate as a non-root user.

2. Log in to the agent node and add the non-root user:

   ```
   puppet resource user <UNIQUE NON-ADMIN USERNAME> ensure=present
   managehome=true password="puppet" groups="Users"
   ```

   **Note:** Each non-root user must have a unique name.

3. Stop the `puppet` service:

   ```
   puppet resource service puppet ensure=stopped enable=false
   ```

   By default, the `puppet` service runs automatically as a root user, so it must be disabled.

4. Change to the non-root user and generate a certificate signing request:

   ```
   puppet agent -t --certname "<UNIQUE NON-ADMIN USERNAME>" --server "<MASTER HOSTNAME>"
   ```

   **Important:** This Puppet run submits a cert request to the master and creates a `.puppet` directory structure in the non-root user’s home directory. If this directory is not created automatically, you must manually create it before continuing.

5. As the non-root user, create a configuration file at `%USERPROFILE%/.puppet/puppet.conf` to specify the agent certname and the hostname of the master:

   ```
   [main]
   certname = <UNIQUE NON-ADMIN USERNAME.hostname>
   server = <MASTER HOSTNAME>
   ```

6. As the non-root user, submit a cert request: `puppet agent -t`. 

© 2020 Puppet, Inc.
7. On the master or in the console, approve the certificate signing request.

**Important:** It's possible to sign the root user certificate in order to allow that user to also manage the node. However, this introduces the possibility of unwanted behavior and security issues. For example, if your site.pp has no default node configuration, running the agent as non-admin could lead to unwanted node definitions getting generated using alt hostnames, a potential security issue. If you deploy this scenario, ensure the root and non-root users never try to manage the same resources, have clear-cut node definitions, ensure that classes scope correctly, and so forth.

8. On the agent node as the non-root user, run Puppet: `puppet agent -t`.

The configuration specified in the catalog is applied to the node.

**Non-root user functionality**
Non-root users can use a subset of functionality. Any operation that requires root privileges, such as installing system packages, can't be managed by a non-root agent.

**‘nix non-root functionality**
On ‘nix systems, as non-root agent you can enforce these resource types:

- `cron` (only non-root cron jobs can be viewed or set)
- `exec` (cannot run as another user or group)
- `file` (only if the non-root user has read/write privileges)
- `notify`
- `schedule`
- `ssh_key`
- `ssh_authorization_key`
- `service`
- `augeas`

**Note:** When running a cron job as non-root user, using the `-u` flag to set a user with root privileges causes the job to fail, resulting in this error message:

```
Notice: /Stage[main]/Main/Node[nonrootuser]/Cron[illegal_action]/ensure:
created must be privileged to use -u
```

You can also inspect these resource types (use `puppet resource <resource type>`):

- `host`
- `mount`
- `package`

**Windows non-root functionality**
On Windows systems as non-admin user, you can enforce these types:

- `exec`
- `file`

**Note:** A non-root agent on Windows is extremely limited as compared to non-root ‘nix. While you can use the above resources, you are limited on usage based on what the agent user has access to do (which isn't much). For instance, you can't create a file\directory in C:\Windows unless your user has permission to do so.

You can also inspect these resource types (use `puppet resource <resource type>`):

- `host`
- `package`
- `user`
- `group`

© 2020 Puppet, Inc.
Managing certificate signing requests

When you install a Puppet agent on a node, the agent automatically submits a certificate signing request (CSR) to the master. You must accept this request to bring before the node under PE management can be added your deployment. This allows Puppet to run on the node and enforce your configuration, which in turn adds node information to PuppetDB and makes the node available throughout the console.

You can approve certificate requests from the PE console or the command line. If DNS altnames are set up for agent nodes, you must approve the CSRs on use the command line interface.

Note: Specific user permissions are required to manage certificate requests:

- To accept or reject CSRs in the console or on the command line, you need the permission Certificate requests: Accept and reject.
- To manage certificate requests in the console, you also need the permission Console: View.

Related information
Installing agents on page 106
You can install Puppet Enterprise agents on *nix, Windows, and macOS.

Managing certificate signing requests in the console
A certificate signing request appears in the console on the Unsigned certs page after you add an agent node to inventory. Accept or reject submitted requests individually or in a batch.

- To manage requests individually, click Accept or Reject.
- To manage the entire list of requests, click Accept All or Reject All. Nodes are processed in batches. If you close the browser window or navigate to another website while processing is in progress, only the current batch is processed.

After you accept the certificate signing request, the node appears in the console after the next Puppet run. To make a node available immediately after you approve the request, run Puppet on demand.

Related information
Running Puppet on demand on page 441
The orchestrator gives you the ability to set up jobs in the console or on the command line to trigger on-demand Puppet runs.

Managing certificate signing requests on the command line
You can view, approve, and reject node requests using the command line.

To view pending node requests on the command line:

$ sudo puppetserver ca list

To sign a pending request:

$ sudo puppetserver ca sign --certname <NAME>

Note: You can use the Puppet Server CA CLI to sign certificates with altnames or auth extensions by default.

Configuring agents
You can add additional configuration to agents by editing /etc/puppetlabs/puppet/puppet.conf directly, or by using the puppet config set sub-command, which edits puppet.conf automatically.

For example, to point the agent at a master called master.example.com, run puppet config set server master.example.com. This command adds the setting server = puppetmaster.example.com to the [main] section of puppet.conf.
To set the certname for the agent, run

```
/opt/puppetlabs/bin/puppet config set certname agent.example.com
```

## Installing compilers

As your Puppet Enterprise infrastructure scales up to 4,000 nodes and beyond, add load-balanced compilers to your installation to increase the number of agents you can manage.

Each compiler increases capacity by 1,500 to 3,000 nodes, until you exhaust the capacity of PuppetDB or the console.

### How compilers work

A single master can process requests and compile code for up to 4,000 nodes. When you exceed this scale, expand your infrastructure by adding compilers to share the workload and compile catalogs faster.

**Important:** Compilers must run the same OS major version, platform, and architecture as the master.

Compilers act as PCP brokers, conveying messages between the orchestrator and Puppet Execution Protocol (PXP) agents. PXP agents connect to PCP brokers running on compilers over port 8142. Status checks on compilers must be sent to port 8140, using `https://<hostname>:8140/status/v1/simple`. 

---

© 2020 Puppet, Inc.
**Components and services running on compilers**

Compilers typically run Puppet Server and PuppetDB services, as well as a file sync client. Older, legacy-style compilers must be converted in order to add PuppetDB.

When triggered by a web endpoint, file sync takes changes from the working directory on the master and deploys the code to a live code directory. File sync then deploys that code to all your compilers, ensuring that all masters in a multi-master configuration remain in sync. By default, compilers check for code updates every five seconds.

The certificate authority (CA) service is disabled on compilers. A proxy service running on the compiler Puppet Server directs CA requests to the master, which hosts the CA in default installations.

Compilers also have:

- The repository for agent installation, `pe_repo`
- The controller profile used with PE client tools
- Puppet Communications Protocol (PCP) brokers to enable orchestrator scale

Logs for compilers are located at `/var/log/puppetlabs/puppetserver/`.

Logs for PCP brokers on compilers are located at `/var/log/puppetlabs/puppetserver/pcp-broker.log`.

**Using load balancers with compilers**

When using more than one compiler, a load balancer can help distribute the load between the compilers and provide a level of redundancy.

Specifics on how to configure a load balancer infrastructure falls outside the scope of this document, but examples of how to leverage haproxy for this purpose can be found in the HAproxy module documentation.

**Load balancing**

PCP brokers run on compilers and connect to PXP agents over port 8142. PCP brokers are built on websockets and require many persistent connections. If you're not using HTTP health checks, we recommend using a round robin or random load balancing algorithm for PXP agent connections to PCP brokers, because PCP brokers don't operate independent of the orchestrator and isolate themselves if they become disconnected. You can check connections with the `/status/v1/simple` endpoint for an error state.

You must also configure your load balancer to avoid closing long-lived connections that have little traffic. In the HAproxy module, you can set the `timeout tunnel` to `15m` because PCP brokers disconnect inactive connections after 15 minutes.

**Using health checks**

The Puppet REST API exposes a status endpoint that can be leveraged from a load balancer health check to ensure that unhealthy hosts do not receive agent requests from the load balancer.

The master service responds to unauthenticated HTTP GET requests issued to `https://<hostname>:8140/status/v1/simple`. The API responds with an HTTP 200 status code if the service is healthy.

If your load balancer doesn't support HTTP health checks, a simpler alternative is to check that the host is listening for TCP connections on port 8140. This ensures that requests aren't forwarded to an unreachable instance of the master, but it does not guarantee that a host is pulled out of rotation if it's deemed unhealthy, or if the service listening on port 8140 is not a service related to Puppet.

**Optimizing workload distribution**

Due to the diverse nature of the network communications between the agent and the master, we recommend that you implement a load balancing algorithm that distributes traffic between compilers based on the number of open connections. Load balancers often refer to this strategy as "balancing by least connections."

© 2020 Puppet, Inc.
Install compilers

Installing a compiler adds the specified node to the PE Infrastructure Agent and PE Compiler node groups and installs the PuppetDB service on the node.

**Before you begin**

The node you want to provision as a compiler must have a Puppet agent installed, or you must be able to connect to a non-agent node with SSH.

To install a FIPS-compliant compiler, install the compiler on a supported platform with FIPS mode enabled. The node must be configured with sufficient available entropy or the installation process fails.

1. **Configure infrastructure agents to connect orchestration agents to the master.**
   a) In the console, click Node groups, and in the PE Infrastructure group, select the PE Infrastructure Agent group.
   b) If you manage your load balancers with agents, on the Rules tab, pin load balancers to the group.
   c) On the Classes tab, find the puppetEnterprise::profile::agent class and specify these parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>manage_puppet_conf</td>
<td>Specify true to ensure that your setting for server_list is configured in the expected location and persists through Puppet runs.</td>
</tr>
<tr>
<td>pcp_broker_list</td>
<td>Hostname for your master and replica, if you have one. Hostnames must include port 8142, for example [&quot;MASTER.EXAMPLE.COM:8142&quot;, &quot;REPLICA.EXAMPLE.COM:8142&quot;].</td>
</tr>
<tr>
<td>master_uris</td>
<td>Hostname for your master and replica, if you have one, for example [&quot;MASTER.EXAMPLE.COM&quot;, &quot;REPLICA.EXAMPLE.COM&quot;]. This setting assumes port 8140 unless you specify otherwise with host:port.</td>
</tr>
<tr>
<td>server_list</td>
<td></td>
</tr>
</tbody>
</table>

   d) Remove any values set for pcp_broker_ws_uris.
   e) Commit changes.
   f) Run Puppet on all agents classified into the PE Infrastructure Agent group.

2. Pin the node that you want to provision to the PE Infrastructure Agent group and run Puppet on the node:

   puppet agent -t
3. On your master logged in as root, run:

```
puppet infrastructure provision compiler <COMPILER_FQDN>
```

You can specify these optional parameters:

- **dns-alt-names** — Comma-separated list of any alternative names that agents use to connect to compilers. The installation uses puppet by default.
  
  **Note:** If your puppet.conf file includes a dns_alt_names entry, you must include the dns-alt-names parameter when provisioning your compiler.

- **no-dns-alt-names** — Prevents the installer from setting the default alternative name, puppet. Use this parameter if you don't allow alternative names (allow-subject-alt-names: false in your ca.conf).

- **use-ssh** — Enables installing on a node that doesn't have a Puppet agent currently installed. You must be able to connect to the node with SSH. You can pair this flag with additional SSH parameters. Run `puppet infrastructure provision --help` for details.

Configure compilers to appropriately route communication between your master and agent nodes.

**Configure compilers**

Compilers must be configured to appropriately route communication between your master and agent nodes.

**Before you begin**

- Install compilers and load balancers.
- If you need DNS aliases for your load balancers, add them to the master.
- Ensure port 8143 is open on the master or on any workstations used to run orchestrator jobs.

1. Configure `pe_repo::compile_master_pool_address` to send agent install requests to the load balancer.

   **Important:** If you have load balancers in multiple data centers, you must configure `compile_master_pool_address` using Hiera, instead of using configuration data in the console, as described in this step. Using either of these methods updates the agent install script URL displayed in the console.

   **Note:** If you are using a single compile master, configure `compile_master_pool_address` with the compile master's fully qualified domain name (FQDN).

   a) In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Master** group.
   b) On the **Configuration data** tab, select the **pe_repo** class and specify parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compile_master_pool_address</td>
<td>Load balancer hostname.</td>
</tr>
</tbody>
</table>

c) Click **Add data** and commit changes.

2. Run Puppet on the compiler, and then on the master.
3. Configure agents to connect orchestration agents to the load balancer.
   a) In the console, click Node groups, and in the PE Infrastructure group, select the PE Agent group.
   b) On the Classes tab, find the puppet_enterprise::profile::agent class and specify parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>manage_puppet_conf</td>
<td>Specify true to ensure that your setting for server_list is configured in the expected location and persists through Puppet runs.</td>
</tr>
<tr>
<td>pcp_broker_list</td>
<td>Hostname for your load balancers. Hostnames must include port 8142, for example [&quot;LOADBALANCER1.EXAMPLE.COM:8142&quot;, &quot;LOADBALANCER2.EXAMPLE.COM:8142&quot;]</td>
</tr>
<tr>
<td>master_uris</td>
<td>Hostname for your load balancers, for example [&quot;LOADBALANCER1.EXAMPLE.COM&quot;, &quot;LOADBALANCER2.EXAMPLE.COM&quot;] This setting assumes port 8140 unless you specify otherwise with host:port.</td>
</tr>
<tr>
<td>server_list</td>
<td>Hostname for your load balancers, for example [&quot;LOADBALANCER1.EXAMPLE.COM&quot;, &quot;LOADBALANCER2.EXAMPLE.COM&quot;]</td>
</tr>
</tbody>
</table>

   c) Remove any values set for pcp_broker_ws_uris.
   d) Commit changes.
   e) Run Puppet on the master, then run Puppet on all agents, or install new agents.

   This Puppet run configures PXP agents to connect to the load balancer.

   Run puppet infrastructure tune on your master and adjust tuning for compilers as needed.

   Related information
   Firewall configuration for large installations with compilers on page 86
   These are the port requirements for large installations with compilers.

Convert existing compilers

If you have legacy compilers, you can improve their usability and scalability by adding PuppetDB. In addition to installing the PuppetDB service, converting an existing compiler adds the node to the PE Compiler node group and unpins it from the PE Master node group.

Before you begin
Open port 5432 from compilers to your master or, in extra-large installations, your PE-PostgreSQL node.

On your master logged in as root, run:

```
puppet infrastructure run convert_legacy_compiler
compiler=<COMPILER_FQDN-1>,<COMPILER_FQDN-2>
```

Tip: To convert all compilers:

```
puppet infrastructure run convert_legacy_compiler all=true
```

Run puppet infrastructure tune on your master and adjust tuning for compilers as needed.

Installing PE client tools

PE client tools are a set of command line tools that let you access Puppet Enterprise services from a workstation that might or might not be managed by Puppet.

The pe-client-tools package is included in the PE installation tarball. When you install, the client tools are automatically installed on the same node as the master.
Client tools versions align with PE versions. For example, if you're running PE 2017.3, use the 2017.3 client tools. In some cases, we might issue patch releases ("x.y.z") for PE or the client tools. You don't need to match patch numbers between PE and the client tools. Only the "x.y" numbers need to match.

**Important:** When you upgrade PE to a new "x.y" version, install the appropriate "x.y" version of PE client tools.

The package includes client tools for these services:

- **Orchestrator** — Allow you to control the rollout of changes in your infrastructure, and provides the interface to the orchestration service. Tools include `puppet-job` and `puppet-app`.
- **Puppet access** — Authenticates you to the PE RBAC token-based authentication service so that you can use other capabilities and APIs.
- **Code Manager** — Provides the interface for the Code Manager and file sync services. Tools include `puppet-code`.
- **PuppetDB CLI** — Enables certain operations with PuppetDB, such as building queries and handling exports.

Because you can safely run these tools remotely, you no longer need to SSH into the master to execute commands. Your permissions to see information and to take action are controlled by PE role-based access control. Your activity is logged under your username rather than under `root` or the `pe-puppet` user.

**Related information**

**Orchestrator configuration files** on page 435
The configuration file for the orchestrator allows you to run commands from the CLI without having to pass additional flags. Whether you are running the orchestrator from the Puppet master or from a separate work station, there are two types of configuration files: a global configuration file and a user-specified configuration file.

**Configure puppet-access** on page 208
The `puppet-access` command allows users to generate and manage authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master. Ensure puppet-access is configured correctly before using it to generate authentication tokens.

**Installing and configuring puppet-code** on page 601
PE automatically installs and configures the `puppet-code` command on your masters as part of the included PE client tools package. You can also set up `puppet-code` on an agent node or on a workstation, customize configuration for different users, or change the configuration settings.

**Supported PE client tools operating systems**
The PE client tools package can be installed on these platforms.

Install PE client tools on a managed workstation

To use the client tools on a system other than the master, where they're installed by default, you can install the tools on a controller node.

**Before you begin**
Controller nodes must be running the same OS as your master and must have an agent installed.

1. In the console, create a controller classification group, for example `PE Controller`, and ensure that its Parent name is set to All Nodes.
2. Select the controller group and add the `puppet_enterprise::profile::controller` class.
3. Pin the node that you want to be a controller to the controller group.
   a) In the controller group, on the Rules tab, in the Certname field, enter the certname of the node.
   b) Click Pin node and commit changes.
4. Run Puppet on the controller machine.

**Related information**
[Create classification node groups](#) on page 297
Create classification node groups to assign classification data to nodes.

Install PE client tools on an unmanaged workstation

You can install the `pe-client-tools` package on any workstation running a supported OS. The workstation OS does not need to match the master OS.

**Before you begin**
Review prerequisites for timekeeping, name resolution, and firewall configuration, and ensure that these ports are available on the workstation.

- **8143** — The orchestrator client uses this port to communicate with orchestration services running on the master.
- **4433** — The Puppet access client uses this port to communicate with the RBAC service running on the master.
- **8170** — If you use the Code Manager service, it requires this port.

Install PE client tools on an unmanaged Linux workstation

1. On the workstation, create the directory `/etc/puppetlabs/puppet/ssl/certs`.
2. On the master, navigate to `/etc/puppetlabs/puppet/ssl/certs/` and copy `ca.pem` to the directory you created on the workstation.
3. On the workstation, make sure file permissions are correct:
   ```
   chmod 444 /etc/puppetlabs/puppet/ssl/certs/ca.pem
   ```
4. Verify that the checksum of `ca.pem` on the workstation matches the checksum of the same file on the master.
5. Download the `pe-client-tools` package for the platform appropriate to your workstation.
6. Use your workstation's package management tools to install the pe-client-tools.
   For example, on RHEL platforms:
   ```
   rpm -Uvh pe-client-tools-<VERSION-and-PLATFORM>.rpm
   ```

Install PE client tools on an unmanaged Windows workstation

You can install the client tools on a Windows workstation using the setup wizard or the command line.

To start using the client tools on your Windows workstation, open the **PE ClientTools Console** from the Start menu.

1. On the workstation, create the directory `C:\ProgramData\PuppetLabs\puppet\etc\ssl\certs`.
   For example:
   ```
   mkdir C:\ProgramData\PuppetLabs\puppet\etc\ssl\certs
   ```
2. On the master, navigate to `/etc/puppetlabs/puppet/ssl/certs/` and copy `ca.pem` to the directory you created on the workstation.
3. On the workstation, make sure the file permissions are set to read-only for `C:\ProgramData\PuppetLabs\puppet\etc\ssl\certs\ca.pem`.

© 2020 Puppet, Inc.
4. Verify that the checksum of ca.pem on the workstation matches the checksum of the same file on the master.
5. Install the client tools using guided setup or the command line.
   • Guided setup
     b. Double-click the pe-client-tools.msi file.
     c. Follow prompts to accept the license agreement and select the installation location.
     d. Click Install.
   • Command line
     b. From the command line, run the installer:

     msiexec /i <PATH TO PE-CLIENT-TOOLS.MSI> TARGETDIR="<INSTALLATION DIRECTORY>"

     TARGETDIR is optional.

**Install PE client tools on an unmanaged macOS workstation**
You can install the client tools on a macOS workstation using Finder or the command line.

1. On the workstation, create the directory /etc/puppetlabs/puppet/ssl/certs.
2. On the master, navigate to /etc/puppetlabs/puppet/ssl/certs/ and copy ca.pem to the directory you created on the workstation.
3. On the workstation, make sure file permissions are correct: chmod 444 /etc/puppetlabs/puppet/ssl/certs/ca.pem
4. Verify that the checksum of ca.pem on the workstation matches the checksum of the same file on the master.
5. Install the client tools using Finder or the command line.
   • Finder
     a. Download the macOS pe-client-tools-package.
     b. Open the pe-client-tools.dmg and click the installer.pkg.
     c. Follow the prompts to install the client tools.
   • Command line
     a. Download the macOS pe-client-tools-package.
     b. Mount the disk image: sudo hdiutil mount <DMGFILE>.
     A line appears ending with /Volumes/puppet-agent-VERSION. This directory location is the mount point for the virtual volume created from the disk image.
     c. Run cd /Volumes/pe-client-tools-VERSION.
     e. Run cd ~ and then run sudo umount /Volumes/pe-client-tools-VERSION.

**Configuring and using PE client tools**
Use configuration files to customize how client tools communicate with the master.

For each client tool, you can create config files for individual machines (global) or for individual users. Configuration files are structured as JSON.

Save configuration files to these locations:
   • Global
     • *nix — /etc/puppetlabs/client-tools/
     • Windows — %ProgramData%\puppetlabs\client-tools

© 2020 Puppet, Inc.
• User
  • *nix — ~/.puppetlabs/client-tools/
  • Windows — %USERPROFILE%\puppetlabs\client-tools

On managed client nodes where the operating system and architecture match the master, you can have PE manage Puppet code and orchestrator global configuration files using the puppet_enterprise::profile::controller class.

For example configuration files and details about using the various client tools, see the documentation for each service.

The configuration file for the orchestrator allows you to run commands from the CLI without having to pass additional flags. Whether you are running the orchestrator from the Puppet master or from a separate workstation, there are two types of configuration files: a global configuration file and a user-specified configuration file.

**Configure puppet-access** on page 208
The puppet-access command allows users to generate and manage authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master. Ensure puppet-access is configured correctly before using it to generate authentication tokens.

**Installing and configuring puppet-code** on page 601
PE automatically installs and configures the puppet-code command on your masters as part of the included PE client tools package. You can also set up puppet-code on an agent node or on a workstation, customize configuration for different users, or change the configuration settings.

---

**Installing external PostgreSQL**

By default, Puppet Enterprise includes its own database backend, PE-PostgreSQL, which is installed alongside PuppetDB. If the load on your PuppetDB node is larger than it can effectively scale to (greater than 20,000 nodes), you can install a standalone instance of PE-PostgreSQL.

In certain limited circumstances, you might choose to configure a PostgreSQL instance that's not managed by PE. Using unmanaged PostgreSQL increases complexity for maintenance and upgrades, so we recommend this configuration only for customers who can't use PE-PostgreSQL.

© 2020 Puppet, Inc.
Install standalone PE-PostgreSQL

If the load on your PuppetDB node is larger than it can effectively scale to (greater than 20,000 nodes), you can install a standalone instance of PE-PostgreSQL.

Before you begin

You must have root access to the node on which you plan to install PE-PostgreSQL, as well as the ability to SSH and copy files to the node.

1. Prepare your pe.conf file by specifying parameters required for PostgreSQL:

   "puppet_enterprise::puppet_master_host": "<MASTER HOSTNAME>"
   "puppet_enterprise::database_host": "<PE-POSTGRESQL NODE HOSTNAME>"

2. Install PE using the --c flag to specify the path to your customized pe.conf file: ./puppet-enterprise-installer --c <PATH_TO_pe.conf>
   The installer hangs halfway through, because it can't contact the database. Leave the process running and proceed to the next step.

3. Copy the pe.conf file you created to the PE-PostgreSQL node and SSH into that node.

4. Run the installer again with the --c flag, using the same pe.conf file: ./puppet-enterprise-installer --c <PATH_TO_pe.conf>
   When the installation process finishes on the PE-PostgreSQL node, the installer automatically resumes installation on the master.
   Tip: If installation fails to resume on the master automatically, connect with SSH to the master and run puppet infrastructure configure.

5. SSH into the master and run Puppet: puppet agent -t
   The master is configured to use the standalone PE-PostgreSQL installation on the PE-PostgreSQL node.

Install unmanaged PostgreSQL

If you use Amazon RDS, or if your business requirements dictate that databases must be managed outside of Puppet, you can configure a PostgreSQL database that’s not managed by PE.

Before you begin

You must have:

- PostgreSQL 9.6 or later.
- The complete certificate authority certificate chain for the external party CA, in PEM format.
- The DNS-addressable name, username, and password for the external PostgreSQL database.

Important: Using unmanaged PostgreSQL increases complexity for maintenance and upgrades, so we recommend it only for customers who can’t use PE-PostgreSQL.

Create the unmanaged PostgreSQL instance

Create the unmanaged PostgreSQL instance, and, if you haven't already, retrieve the necessary certificate chain and credentials from your database administrator.

For example, for RDS, the root certificate is available here.

Create PE databases on the unmanaged PostgreSQL instance

1. Log in to the unmanaged PostgreSQL instance with the client of your choice.
2. Create databases for the orchestrator, RBAC, activity service, and the node classifier.

```sql
CREATE USER "pe-inventory" PASSWORD '<PASSWORD>';  
GRANT "pe-inventory" TO <ADMIN USER>;  
CREATE DATABASE "pe-inventory" OWNER "pe-inventory"  
ENCODING 'utf8' LC_CTYPE 'en_US.utf8' LC_COLLATE 'en_US.utf8' template template0;

CREATE USER "pe-puppetdb" PASSWORD '<PASSWORD>';  
GRANT "pe-puppetdb" TO <ADMIN USER>;  
CREATE DATABASE "pe-puppetdb" OWNER "pe-puppetdb"  
ENCODING 'utf8' LC_CTYPE 'en_US.utf8' LC_COLLATE 'en_US.utf8' template template0;

CREATE USER "pe-orchestrator" PASSWORD '<PASSWORD>';  
GRANT "pe-orchestrator" TO <ADMIN USER>;

CREATE EXTENSION pg_trgm; © 2020 Puppet, Inc.  
CREATE EXTENSION plpgsql;
```
Install PE using the `-c` flag to specify the path to a customized `pe.conf` file with required PostgreSQL parameters:

```
./puppet-enterprise-installer -c <PATH_TO_pe.conf>
```

Establish SSL between PE and the unmanaged PostgreSQL instance

**Before you begin**

Install PE using the `-c` flag to specify the path to a customized `pe.conf` file with required PostgreSQL parameters:

```
./puppet-enterprise-installer -c <PATH_TO_pe.conf>
```

1. Log in to the master and stop the agent service:

   ```
   /opt/puppetlabs/puppet/bin/puppet resource service puppet ensure=stopped
   ```

2. On the master, create a location to store the CA cert from the external PostgreSQL instance, for example `/etc/puppetlabs/puppet/ssl/`

3. Transfer the CA cert from the unmanaged PostgreSQL instance to the directories that you created.

4. Specify ownership and permissions for the certificate and directories.

   ```
   chown -R pe-puppet:pe-puppet <PATH TO DIRECTORY>
   chmod 664 <PATH TO DIRECTORY>/<CERT NAME>
   ```

5. Modify your `pe.conf` file to specify database properties.

   ```
   "puppet_enterprise::profile::console::database_properties": "?
   ssl=true&sslfactory=org.postgresql.ssl.jdbc4.LibPQFactory&sslmode=verify-full&sslrootcert=<PATH TO EXTERNAL POSTGRESQL CA CERT>
   "puppet_enterprise::profile::puppetdb::database_properties": "?
   ssl=true&sslfactory=org.postgresql.ssl.jdbc4.LibPQFactory&sslmode=verify-full&sslrootcert=<PATH TO EXTERNAL POSTGRESQL CA CERT>
   "puppet_enterprise::profile::orchestrator::database_properties": "?
   ssl=true&sslfactory=org.postgresql.ssl.jdbc4.LibPQFactory&sslmode=verify-full&sslrootcert=<PATH TO EXTERNAL POSTGRESQL CA CERT>
   "puppet_enterprise::database_ssl": true
   "puppet_enterprise::database_cert_auth": false
   ```

6. On the master, run Puppet.

7. On the master, start the agent service: `puppet resource service puppet ensure=running`

**Uninstalling**

Puppet Enterprise includes a script for uninstalling. You can uninstall component infrastructure nodes or from agent nodes.

**Uninstall infrastructure nodes**

The `puppet-enterprise-uninstaller` script is installed on the master. In order to uninstall, you must run the uninstaller on each infrastructure node.

By default, the uninstaller removes the software, users, logs, cron jobs, and caches, but it leaves your modules, manifests, certificates, databases, and configuration files in place, as well as the home directories of any users it removes.

1. From the infrastructure node that you want to uninstall, from the command line as root, navigate to the installer directory and run the uninstall command: `$ sudo ./puppet-enterprise-uninstaller`

   **Note:** If you don't have access to the installer directory, you can run `/opt/puppetlabs/bin/puppet-enterprise-uninstaller`.

2. Follow prompts to uninstall.
3. (Optional) If you don’t uninstall the master, and you plan to reinstall on an infrastructure node at a later date, remove the agent certificate for that component from the master. On the master: puppetserver ca clean <PE COMPONENT CERT NAME>.

**Uninstall agents**

You can remove the agent from nodes that you no longer want to manage.

**Note:** Uninstalling the agent doesn’t remove the node from your environment. To completely remove all traces of a node, you must also purge the node.

**Related information**

[Adding and removing agent nodes](#) on page 288

After you install a Puppet agent on a node, accept its certificate signing request and begin managing it with Puppet Enterprise (PE). Or remove nodes that you no longer need.

**Uninstall *nix agents**

The *nix agent package includes an uninstall script, which you can use when you're ready to retire a node.

1. On the agent node, run the uninstall script: run `/opt/puppetlabs/bin/puppet-enterprise-uninstaller`
2. Follow prompts to uninstall.
3. (Optional) If you plan to reinstall on the node at a later date, remove the agent certificate for the agent from the master: puppetserver ca clean <AGENT CERT NAME>

**Uninstall Windows agents**

To uninstall the agent from a Windows node, use the Windows Add or Remove Programs interface, or uninstall from the command line.

Uninstalling the agent removes the Puppet program directory, the agent service, and all related registry keys. The data directory remains intact, including all SSL keys. To completely remove Puppet from the system, manually delete the data directory.

1. Use the Windows Add or Remove Programs interface to remove the agent.
2. (Optional) If you plan to reinstall on the node at a later date, remove the agent certificate for the agent from the master: puppetserver ca clean <AGENT CERT NAME>

**Uninstall macOS agents**

Use the command line to remove all aspects of the agent from macOS nodes.

1. On the agent node, run these commands:

```
rmm -rf /var/log/puppetlabs
rm -rf /var/run/puppetlabs
pkgutil --forget com.puppetlabs.puppet-agent
launchctl remove puppet
rm -rf /Library/LaunchDaemons/com.puppetlabs.puppet.plist
launchctl remove pxp-agent
rm -rf /Library/LaunchDaemons/com.puppetlabs pxp-agent.plist
rm -rf /etc/puppetlabs
rm -rf /opt/puppetlabs
```
2. (Optional) If you plan to reinstall on the node at a later date, remove the agent certificate for the agent from the master: puppetserver ca clean <AGENT CERT NAME>
Uninstaller options

You can use the following command-line flags to change the uninstaller's behavior.

- `-p` — Purge additional files. With this flag, the uninstaller also removes all configuration files, modules, manifests, certificates, the home directories of any users created by the installer, and the Puppet public GPG key used for package verification.
- `-d` — Also remove any databases created during installation.
- `-h` — Display a help message.
- `-n` — Run in `noop` mode; show commands that would have been run during uninstallation without actually running them.
- `-y` — Don't ask to confirm uninstallation, assuming an answer of yes.

To remove every trace of PE from a system, run:

```
$ sudo ./puppet-enterprise-uninstaller -d -p
```

Upgrading

To upgrade your Puppet Enterprise deployment, you must upgrade both the infrastructure components and agents.

- [Upgrading Puppet Enterprise](#) on page 138
  Upgrade your PE installation as new versions become available.
- [Upgrading agents](#) on page 145
  Upgrade your agents as new versions of Puppet Enterprise become available. The puppet_agent module helps automate upgrades, and provides the safest upgrade. Alternatively, you can upgrade individual nodes using a script.

Upgrading Puppet Enterprise

Upgrade your PE installation as new versions become available.

Upgrade paths

These are the valid upgrade paths for PE.

<table>
<thead>
<tr>
<th>If you're on version...</th>
<th>Upgrade to...</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019.8 (latest)</td>
<td>You're up to date!</td>
<td></td>
</tr>
<tr>
<td>2019.y</td>
<td>latest</td>
<td></td>
</tr>
<tr>
<td>2018.1.2 or later</td>
<td>latest</td>
<td>You must have version 2018.1.2 or later in order to complete prerequisites for upgrade to the latest version.</td>
</tr>
<tr>
<td>2018.1.3 or later with disaster recovery</td>
<td>2018.1.z</td>
<td>With disaster recovery enabled, you must have version 2018.1.3 in order to upgrade to the latest version. Alternatively, you can forget and then recreate your replica after upgrade.</td>
</tr>
<tr>
<td>2018.1.0 or 2018.1.1</td>
<td>2018.1</td>
<td></td>
</tr>
<tr>
<td>2017.3.z</td>
<td>2018.1</td>
<td></td>
</tr>
<tr>
<td>2017.2.z</td>
<td>2018.1</td>
<td></td>
</tr>
</tbody>
</table>
If you're on version... | Upgrade to... | Notes
---|---|---
2017.1.z | 2018.1 | 
2016.5.z | 2018.1 | 
2016.4.10 or later | 2018.1 | 
2016.4.9 or earlier | 2016.4.z, then 2018.1 | To upgrade to 2018.1 from 2015.2.z through 2016.4.9, you must first upgrade to the latest 2016.4.z. 
2016.2.z | | 
2016.1.z | | 
2015.3.z | | 
2015.2.z | | 
3.8.x | 2016.4.z, then 2018.1 | To upgrade from 3.8.x, you must first migrate to the latest 2016.4.z. This upgrade requires a different process than upgrades from other versions.

### Upgrade cautions

These are the major changes to PE since the last long-term support release, 2018.1. Review these recommendations and plan accordingly before upgrading to this version.

**Important:** Always back up your installation before performing any upgrade.

**Retired master platforms in 2019.8**

Support for Enterprise Linux 6 and Ubuntu 16.04 as a master platform was removed in 2019.8. If your master is installed on one of these platforms, you must update the operating system before you can upgrade to this version of PE.

Follow these steps to upgrade from an unsupported master platform.

1. Back up your existing installation.
2. Configure a new node with a supported master platform, for example Enterprise Linux 7 or 8, or Ubuntu 18.04.
3. Install your current PE version on the new node.
4. Restore your installation on the new master using the backup you created.
5. Upgrade to the latest PE version.
6. If you have compilers, reprovision them.
7. If you have a replica, forget and then reprovision it.

**Related information**

- [Back up your infrastructure](#) on page 647
  PE backup creates a copy of your Puppet master, including configuration, certificates, code, and PuppetDB.
- [Restore your infrastructure](#) on page 648
  Use the restore commands to migrate your PE master to a new host or to recover from system failure.
- [Upgrade a standard installation](#) on page 143
  To upgrade, run the PE installer on your master, and then upgrade any additional components.
- [Install compilers](#) on page 127
  Installing a compiler adds the specified node to the PE Infrastructure Agent and PE Compiler node groups and installs the PuppetDB service on the node.
- [Forget a replica](#) on page 191
  Forgetting a replica cleans up classification and database state, preventing degraded performance over time.
- [Provision and enable a replica](#) on page 187

© 2020 Puppet, Inc.
Provisioning a replica duplicates specific components and services from the master to the replica. Enabling a replica activates most of its duplicated services and components, and instructs agents and infrastructure nodes how to communicate in a failover scenario.

**PuppetDB migrations in PE 2019.1, 2019.3, and 2019.7**

Upgrades to PE 2019.1, 2019.3, and 2019.7 involve database migrations that can slow upgrade significantly. Deleting PuppetDB reports and truncating the resource events table before you upgrade can reduce migration time and lessen your downtime.

If you're upgrading from 2019.7 or later, or PE LTS version 2018.1.15 or later, you can run a packaged delete reports command before upgrade. For other versions that don't include the delete reports command, you can manually delete reports by following these steps.

1. Stop the PuppetDB service: `service pe-puppetdb stop`
2. On your PE-PostgreSQL server, create a file named `/tmp/delete-reports.sql` and set it to be owned by the `pe-postgres` user (`chown pe-postgres:pe-postgres /tmp/delete-reports.sql`).
3. Add contents to the `.sql` file according to your PE version.

**PE versions earlier than 2019.3**

```sql
BEGIN TRANSACTION;
ALTER TABLE certnames DROP CONSTRAINT IF EXISTS certnames_reports_id_fkey;
UPDATE certnames SET latest_report_id = NULL;
TRUNCATE TABLE reports CASCADE;

ALTER TABLE certnames
ADD CONSTRAINT certnames_reports_id_fkey FOREIGN KEY (latest_report_id) REFERENCES reports(id) ON DELETE SET NULL;

COMMIT TRANSACTION;
```

**PE 2019.3 through 2019.7**

```sql
BEGIN TRANSACTION;
ALTER TABLE certnames DROP CONSTRAINT IF EXISTS certnames_reports_id_fkey;
UPDATE certnames SET latest_report_id = NULL;

DO $$ DECLARE
r RECORD;
BEGIN
FOR r IN (SELECT tablename FROM pg_tables WHERE tablename LIKE 'resource_events_%') LOOP
EXECUTE 'DROP TABLE ' || quote_ident(r.tablename);
END LOOP;
END $$;
TRUNCATE TABLE reports CASCADE;

ALTER TABLE certnames
ADD CONSTRAINT certnames_reports_id_fkey FOREIGN KEY (latest_report_id) REFERENCES reports(id) ON DELETE SET NULL;

COMMIT TRANSACTION;
```

4. Run the command: `su - pe-postgres -s /bin/bash -c "'/opt/puppetlabs/server/bin/psql -d pe-puppetdb -f /tmp/delete-reports.sql"'`
Java 11 upgrade in PE 2019.3
PE 2019.3 includes an upgrade from Java version 8 to version 11. If you've customized PE Java services, or use plug-ins that include Java code, test PE 2019.3 and later thoroughly in a non-production environment before upgrading.

Orchestrator memory use increase in PE 2019.2
Puppet orchestrator uses more memory in version 2019.2 than in previous versions due to the addition of a Java virtual machine (JVM), which enables new features and functionalities such as plans. If your memory use is near capacity when running PE 2019.1 or older versions, allocate additional memory before upgrading to PE 2019.2.

Additionally, take care when writing plans, as they can require more memory than is allocated to the orchestrator. To work around this issue, rewrite the plan or increase the memory allocated to the orchestrator.

PostgreSQL 11 upgrade in PE 2019.2
PE 2019.2.0 includes an upgrade from pe-postgresql version 9.6 to version 11. This upgrade involves a datastore migration that requires extra disk space (110% of the current 9.6 datastore) and extra time to upgrade (roughly two and four minutes of additional time per 10GB of datastore size). The installer issues a warning and cancels the upgrade if there is insufficient space.

To review the size of your PostgreSQL installation as well as the size and number of available bytes for the partition, run facter -p pe_postgresql_info on the node that runs the pe-postgresql service.

To speed the migration and optimize queries, clean up the PE-PosgreSQL database prior to upgrade by applying the pe_databases module to nodes running the pe-postgresql service. For best results, apply the module at least one week prior to upgrade to allow the module's maintenance schedule enough time to clean all databases.

After upgrading, you can optionally remove packages and directories associated with older PostgreSQL versions with the command puppet infrastructure run remove_old_postgresql_versions. If applicable, the installer prompts you to complete this cleanup.

Note: If you use an external PostgreSQL instance not managed by PE, you must separately upgrade the instance to PostgreSQL 11. For more information, see Upgrading PostgreSQL.

TLSv1 and v1.1 disabled in PE 2019.1
As of PE 2019.1, TLSv1 and TLSv1.1 is now disabled by default to comply with security regulations. You must enable TLSv1 to upgrade agents on these platforms:

- AIX
- CentOS 5
- RHEL 5
- SLES 11
- Solaris 10
- Windows Server 2008 R2

Certificate architecture and handling in PE 2019.0
PE 2019.0 and later, courtesy of Puppet Server, uses an intermediate certificate authority architecture by default. When you upgrade to PE 2019.0 or later, you have several options for whether and when to adopt the new intermediate certificate architecture:

- To upgrade to 2019.0 or later and keep your existing CA, upgrade infrastructure nodes and agents as normal. You can continue to use pre-6.x agents with a Puppet 6.x or PE 2019.0 or later master as long as you don't regenerate certificates.

- To migrate to 2019.0 or later and keep your existing CA, install the new version and copy /etc/puppetlabs/puppet/ssl from your old master. You can continue to use pre-6.x agents with a Puppet 6.x or PE 2019.0 or later master as long as you don't regenerate certificates.

- To adopt the new CA architecture, upgrade both your master and agents, and then regenerate certificates. If you don't upgrade all of your nodes to 6.x, don't regenerate certificates, because pre-6.x agents won't work with the new CA architecture.
MCollective removal in PE 2019.0

If you're upgrading from a 2018.1 installation with MCollective enabled, you must take additional steps to ensure a successful upgrade.

Before upgrade

- **Remove MCollective** from nodes in your infrastructure. If any nodes are configured with MCollective or ActiveMQ profiles when you attempt to upgrade, the installer halts and prompts you to remove the profiles. For example, remove PE MCollective node group and any of the deprecated parameters:
  - mcollective_middleware_hosts
  - mcollective
  - mcollective_middleware_port
  - mcollective_middleware_user
  - mcollective_middleware_password

  **Tip:** If your PuppetDB includes outdated catalogs for nodes that aren't currently being managed, the installer might report that MCollective is active on those nodes. You can deactivate the nodes with `puppet node deactivate` or use Puppet to update the records.

After upgrade

- **Manually remove these node groups:**
  - PE MCollective
  - PE ActiveMQ Broker
  - Any custom node group you created for ActiveMQ hubs
  - If you customized classification with references to MCollective or ActiveMQ profiles, remove the profiles from your classification. In this version of PE, nodes that include MCollective or ActiveMQ profiles trigger a warning during agent runs. Future versions of PE that remove the profiles completely can trigger failures in catalog compilation if you leave the profiles in place.

Removing MCollective

Remove MCollective and its related files from the nodes in your infrastructure. You must have PE version 2018.1.1 or later to complete this task.

**Note:** This procedure does not remove your MCollective or ActiveMQ log files.

1. In the console, click **Node groups**, and select the node group **PE Infrastructure**.
2. On the **Configuration** tab, find the **puppet_enterprise** class. Select the **mcollective** parameter and edit its value to **absent**.

<table>
<thead>
<tr>
<th>Class</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppet_enterprise</td>
<td>mcollective</td>
<td>absent</td>
</tr>
</tbody>
</table>

3. Click **Add parameter** and commit the change.
4. Set up a job and run Puppet on the **PE Infrastructure** node group to enforce your changes.

   The server components of MCollective, including pe-activemq and the peadmin user, are removed from the master and the MCollective service on agents is stopped. You must complete the upgrade to 2019.0 or later to completely remove MCollective from agents.

Test modules before upgrade

To ensure that your modules work with the newest version of PE, update and test them with Puppet Development Kit (PDK) before upgrading.

**Before you begin**

If you are already using PDK, your modules should pass validation and unit tests with your currently installed version of PDK.
Update PDK with each new release to ensure compatibility with new versions of PE.

1. Download and install PDK. If you already have PDK installed, this updates PDK to its latest version. For detailed instructions and download links, see the installing instructions.

2. If you have not previously used PDK with your modules, convert them to a PDK compatible format. This makes changes to your module to enable validation and unit testing with PDK. For important usage details, see the converting modules documentation.
   For example, from within the module directory, run:
   ```
pdk convert
   ```

3. If your modules are already compatible with PDK, update them to the latest module template. If you converted modules in step 2, you do not need to update the template. To learn more about updating, see the updating module templates documentation.
   For example, from within the module directory, run:
   ```
pdk update
   ```

4. Validate and run unit tests for each module, specifying the version of PE you are upgrading to. When specifying a PE version, be sure to specify at least the year and the release number, such as 2018.1. For information about module validations and testing, see the validating and testing modules documentation.
   For example, from within the module directory, run:
   ```
pdk validate
pdk test unit
   ```
   The `pdk test unit` command verifies that testing dependencies and directories are present and runs the unit tests that you write. It does not create unit tests for your module.

5. If your module fails validation or unit tests, make any necessary changes to your code.

After you’ve verified that your modules work with the new PE version, you can continue with your upgrade.

**Upgrade a standard installation**

To upgrade, run the PE installer on your master, and then upgrade any additional components.

**Before you begin**

Back up your PE installation.

1. Optional: Speed upgrade by cleaning up PuppetDB reports. On your master, run `/opt/puppetlabs/bin/puppetdb delete-reports`
   If the command fails to execute, you’re likely using a version of PuppetDB that doesn’t yet include the command. See Upgrade cautions on page 139 for manual steps.

2. **Download** the tarball appropriate to your operating system and architecture.

3. Unpack the installation tarball: `tar -xf <tarball>`
   You need about 1 GB of space to untar the installer.

4. From the installer directory, run the installer: `sudo ./puppet-enterprise-installer`
   - If your master is not in the production environment, specify the environment: `sudo ./puppet-enterprise-installer --pe_environment <MASTER_ENVIRONMENT>`
   - To specify a different `pe.conf` file other than the existing file, use the `-c` flag: `sudo ./puppet-enterprise-installer -c <FULL PATH TO pe.conf>`

   With this flag, your previous `pe.conf` is backed up to `/etc/puppetlabs/enterprise/conf.d/<TIMESTAMP>.conf` and a new `pe.conf` is created at `/etc/puppetlabs/enterprise/conf.d/pe.conf`.

© 2020 Puppet, Inc.
5. If prompted, change the console administrator password: `puppet infrastructure console_password --password=<MY_PASSWORD>`
   For security purposes, you’re prompted to change the password if you didn’t do so when you originally installed. If you don’t change the password, the console administrator account is revoked.

6. If you have compilers, on your master logged in as root, run: `puppet infrastructure upgrade compiler <COMPILER_FQDN-1>,<COMPILER_FQDN-2>`
   • To upgrade all compilers simultaneously: `puppet infrastructure upgrade compiler --all`
   • To specify the location of an authentication token other than the default: `puppet infrastructure upgrade compiler <COMPILER_FQDN> --token-file <PATH_TO_TOKEN>`

7. Upgrade these additional PE infrastructure components.
   • Agents
   • PE client tools — Install the appropriate version of client tools that matches the PE version you upgraded to.

8. In disaster recovery installations, upgrade your replica.
   The replica is temporarily unavailable to serve as backup during this step, so you should time upgrading your replica to minimize risk.
   a) On your master logged in as root, run: `puppet infrastructure upgrade replica <REPLICA_FQDN>`
      To specify the location of an authentication token other than the default: `puppet infrastructure upgrade replica <REPLICA_FQDN> --token-file <PATH_TO_TOKEN>`
   b) After the replica upgrade successfully completes, verify that master and replica services are operational. On your master, run: `/opt/puppetlabs/bin/puppet-infra status`
   c) If your replica reports errors, reinitialize the replica. On your replica, run: `/opt/puppetlabs/bin/puppet-infra reinitialize replica -y`

9. Optional: Convert legacy compilers to the new style compiler running the PuppetDB service.
   Converting your compilers reduces bottlenecks and improves scalability in large and extra-large installations.
   a) Open port 5432 from compilers to your master or, in extra-large installations, your PE-PostgreSQL node.
   b) On your master logged in as root, run: `puppet infrastructure run convert_legacy_compiler compiler=<COMPILER_FQDN-1>,<COMPILER_FQDN-2>`
      or `puppet infrastructure run convert_legacy_compiler all=true`

Back up your infrastructure on page 647
PE backup creates a copy of your Puppet master, including configuration, certificates, code, and PuppetDB.

Migrate from a split to a standard installation
Split installations, where the master, console, and PuppetDB are installed on separate nodes, are no longer supported as of PE version 2019.2. Before upgrading to 2019.2 or later, migrate from an existing split installation to a standard (formerly called monolithic) installation—with or without compilers—and a standalone PE-PostgreSQL node.

Before you begin
You must be running a version of PE on all infrastructure nodes that includes the `puppet infrastructure run` command. To verify that this command is available on your systems, run `puppet infrastructure run --help`.

The `puppet infrastructure run` command leverages built-in Bolt plans to automate certain management tasks. To use this command, you must be able to connect using SSH from your master to any nodes that the command modifies. You can establish an SSH connection using key forwarding, a local key file, or by specifying keys in `.ssh/config` on your master. For more information, see Bolt OpenSSH configuration options.

Important: The migration command used in this task automates a number of manual steps, including editing `pe.conf`, unpinning and uninstalling packages from affected infrastructure nodes, and running Puppet multiple
times. Treat this process as you would any major migration by thoroughly testing it in an environment that's as similar to your production environment as possible.

1. On your master, verify that `pe.conf` contains correct information for `console_host`, `puppetdb_host`, and `database_host`. The migration command uses this information to correctly migrate these nodes.

   **Note:** If your split PE installation includes multiple standalone PuppetDB nodes, the migration command will fail with an error.

2. Make sure that the master can connect via SSH to your console node, PuppetDB node, and (if present) standalone PE-PostgreSQL node.

3. On your master logged in as root, run `puppet infrastructure run migrate_split_to_mono`

   You can specify this optional parameter:

   ```
   • `tmpdir` — Path to a directory to use for uploading and executing temporary files.
   ```

   After completion, your master is running the console and PuppetDB services and you can retire or repurpose the old console node. If you did not start with a standalone PE-PostgreSQL node, your old PuppetDB node now functions in that capacity. If you did start with a standalone PE-PostgreSQL node, it continues to function in that capacity and you can retire or repurpose the old PuppetDB node.

### Upgrading PostgreSQL

If you use the default PE-PostgreSQL database installed alongside PuppetDB, you don't have to take special steps to upgrade PostgreSQL. However, if you have a standalone PE-PostgreSQL instance, or if you use a PostgreSQL instance not managed by PE, you must take extra steps to upgrade PostgreSQL.

You must upgrade a standalone PE-PostgreSQL instance each time you upgrade PE. To upgrade a standalone PE-PostgreSQL instance, simply run the installer on the PE-PostgreSQL node first, then proceed with upgrading the rest of your infrastructure.

You must upgrade a PostgreSQL instance not managed by PE only when there's an upgrade to PostgreSQL in PE. To upgrade an unmanaged PostgreSQL instance, use one of these methods:

- Back up databases, wipe your old PostgreSQL installation, install the latest version of PostgreSQL, and restore the databases.
- Back up databases, set up a new node with the latest version of PostgreSQL, restore databases to the new node, and reconfigure PE to point to the new `database_host`.
- Run `pg_upgrade` to get from the older PostgreSQL version to the latest version.

### Upgrading agents

Upgrade your agents as new versions of Puppet Enterprise become available. The `puppet_agent` module helps automate upgrades, and provides the safest upgrade. Alternatively, you can upgrade individual nodes using a script.

**Note:** Before upgrading agents, verify that the master and agent software versions are compatible. Then after upgrade, run Puppet on your agents as soon as possible to verify that agents have the correct configuration and that your systems are behaving as expected.

#### Setting your desired agent version

To upgrade your master but use an older agent version that is still compatible with the new master, define a `pe_repo::platform::<AGENT_OS_VERSION_ARCHITECTURE>` class with the `agent_version` variable set to your desired agent version.

To ensure your agents are always running the same version as your master, in the `puppetlabs-puppet_agent` module, set the `package_version` variable for the `puppet_agent` class to `auto`. This causes agents to automatically upgrade themselves on their first Puppet run after a master upgrade.

Upgrading Puppet Enterprise on page 138
Upgrade your PE installation as new versions become available.

Upgrade agents using the puppet_agent module
The puppetlabs-puppet_agent module, available from the Forge, enables you to upgrade multiple *nixor Windows agents at one time. The module handles all the latest version-to-version upgrades.

Important: For the most reliable upgrade, always use the latest version of the puppet_agent module to upgrade agents. Test the upgrade on a subset of agents, and after you verify the upgrade, upgrade remaining agents.

1. On your master, download and install the puppetlabs-puppet_agent module:
   ```bash
   puppet module install puppetlabs-puppet_agent
   ```

2. Configure the master to download the agent version you want to upgrade.
   a) In the console, click Node groups, and in the PE Infrastructure group, select the PE Master group.
   b) On the Classes tab, in the Add a new class field, enter pe_repo, and select the appropriate repo class from the list of classes.
      Repo classes are listed as pe_repo::platform::<AGENT_OS_VERSION_ARCHITECTURE>.
      To specify a particular agent version, set the agent_version variable using an X.Y.Z format (for example, 5.5.14). When their version is set explicitly, agents do not automatically upgrade when you upgrade your master.
   c) Click Add class and commit changes.
   d) On your master, run Puppet to configure the newly assigned class:
      ```bash
      puppet agent -t
      ```
      The new repo is created in /opt/puppetlabs/server/data/packages/public/<PE VERSION>/<PLATFORM>.

3. Click Node groups, click Add group, specify options for a new upgrade node group, and then click Add.
   a) Parent name — Select the name of the classification node group that you want to set as the parent to this group, in this case, All Nodes.
   b) Group name — Enter a name that describes the role of this classification node group, for example, agent_upgrade.
   c) Environment — Select the environment your agents are in.
   d) Environment group — Do not select this option.

4. Click the link to Add membership rules, classes, and variables.
5. On the Rules tab, create a rule to add the agents that you want to upgrade to this group, click Add Rule, and then commit changes.
   For example:
   a) Fact — osfamily
   b) Operator — =
   c) Value — RedHat

6. Still in the agent upgrade group, on the Classes tab, add the puppet_agent class, and click Add class.
   If you don’t immediately see the class, click Refresh to update the classifier.

Note: If you’ve changed the prefix parameter of the pe_repo class in your PE Master node group, set the puppet-agent source parameter of the upgrade group to https://<MASTER HOSTNAME>:8140/<Prefix>.
7. In the **puppet_agent** class, specify the version of the `puppet-agent` package version that you want to install, then commit changes.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>package_version</code></td>
<td>The <code>puppet-agent</code> package version to install, for example 5.3.3.</td>
</tr>
<tr>
<td></td>
<td>Set this parameter to <code>auto</code> to install the same agent version that is installed on your master.</td>
</tr>
</tbody>
</table>

8. On the agents that you're upgrading, run Puppet: `/opt/puppet/bin/puppet agent -t`

After the Puppet run, you can verify the upgrade with `/opt/puppetlabs/bin/puppet --version`

**Upgrade agents using a script**

To upgrade an individual node, for example to test or troubleshoot, you can upgrade directly from the node using a script. This method relies on a package repository hosted on your master.

**Note:** If you encounter SSL errors during the upgrade process, ensure your agent's OpenSSL is up to date and matches the master's version. You can check the master's OpenSSL versions with `/opt/puppetlabs/puppet/bin/openssl version` and the agent's version with `openssl version`.

**Upgrade a *nix agent using a script**

You an upgrade an individual *nix agent using a script.

1. Configure the master to download the agent version you want to upgrade.
   a) In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Master** group.
   b) On the **Classes** tab, in the **Add a new class** field, enter `pe_repo`, and select the appropriate repo class from the list of classes.

   Repo classes are listed as `pe_repo::platform::<AGENT_OS_VERSION_ARCHITECTURE>`.

   To specify a particular agent version, set the `agent_version` variable using an `X.Y.Z` format (for example, `5.5.14`). When their version is set explicitly, agents do not automatically upgrade when you upgrade your master.
   c) Click **Add class** and commit changes.
   d) On your master, run Puppet to configure the newly assigned class: `puppet agent -t`

   The new repo is created in `/opt/puppetlabs/server/data/packages/public/<PE VERSION>/<PLATFORM>/`.

2. SSH into the agent node you want to upgrade.
3. Run the upgrade command appropriate to the operating system.

   • Most *nix

     Bash

     cacert="$(puppet config print localcacert)"
     uri="https://$(puppet config print server):8140/packages/current/install.bash"

     curl --cacert "$cacert" "$uri" | sudo bash

   • Mac OS X, Solaris, and AIX

     Bash

     cacert="$(puppet config print localcacert)"
     uri="https://$(puppet config print server):8140/packages/current/install.bash"

     curl --cacert "$cacert" "$uri" | sudo bash

PE services restarts automatically after upgrade.

**Upgrade a Windows agent using a script**

You can upgrade an individual Windows agent using a script. For Windows, this method is riskier than using the puppet_agent module to upgrade, because you must manually complete and verify steps that the module handles automatically.

**Note:** The `<MASTER HOSTNAME>` portion of the installer script—as provided in the following example—refers to the FQDN of the master. The FQDN must be fully resolvable by the machine on which you're installing or upgrading the agent.

1. Stop the Puppet service and the PXP agent service.
2. On the Windows agent, run the install script:

   ```powershell
   ```

3. Verify that Puppet runs are complete.
4. Restart the Puppet service and the PXP agent service.

**Upgrade agents without internet access**

If you don't have access to the internet beyond your infrastructure you can download the appropriate agent tarball from an internet-connected system and then upgrade using a script.

**Before you begin**

Download the appropriate agent tarball from an internet-connected system.

1. On your master, copy the agent tarball to `/opt/puppetlabs/server/data/packages/public/<PE VERSION>/<PLATFORM>`.
2. Run Puppet: `puppet agent -t`
3. Follow the steps to **Upgrade agents using a script** on page 147.
Upgrading the agent independent of PE

You can optionally upgrade the agent to a newer version than the one packaged with your current PE installation.

For details about Puppet agents versions that are tested and supported for PE, see the PE component version table.

The agent version is specified on a platform-by-platform basis in the PE Master node group, in any pe_repo::platform class, using the agent_version parameter.

When you install new nodes or upgrade existing nodes, the agent install script installs the version of the agent specified for its platform class. If a version isn’t specified for the node’s platform, the script installs the default version packaged with your current version of PE.

Note: To install nodes without internet access, download the agent tarball for the version you want to install, as specified using the agent_version parameter.

The platform in use on your master requires special consideration. The agent version used on your master must match the agent version used on other infrastructure nodes, including compilers and replicas, otherwise your master won’t compile catalogs for these nodes.

To keep infrastructure nodes synced to the same agent version, if you specify a newer agent_version for your master platform, you must either:

- (Recommended) Upgrade the agent on your master—and any existing infrastructure nodes—to the newer agent version. You can upgrade these nodes by running the agent install script.
- Manually install the older agent version used on your master on any new infrastructure nodes you provision. You can’t install these nodes using the agent install script, because the script uses the agent version specified for the platform class, instead of the master’s current agent version. Manual installation requires configuring puppet.conf, DNS alt names, CSR attributes, and other relevant settings.

## Configuring Puppet Enterprise

- **Methods for configuring Puppet Enterprise** on page 151
  After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

- **Configuring and tuning Puppet Server** on page 153
  After you've installed Puppet Enterprise, optimize it for your environment by configuring and tuning Puppet Server settings as needed.

- **Configuring and tuning the console** on page 158
  After installing Puppet Enterprise, you can change product settings to customize the console's behavior, adjust to your team's needs, and improve performance. Many settings can be configured in the console itself.

- **Configuring and tuning security settings** on page 161
  Ensure your PE environment is secure by configuring security settings.

- **Configuring and tuning PuppetDB** on page 163
  After you've installed Puppet Enterprise, optimize it for your environment by configuring and tuning PuppetDB configuration as needed.

- **Configuring and tuning orchestration** on page 165
  After installing PE, you can change some default settings to further configure the orchestrator and pe-orchestration-services.

- **Configuring proxies** on page 168
  You can work around limited internet access by configuring proxies at various points in your infrastructure, depending on your connectivity limitations.

- **Configuring Java arguments** on page 169
  You might need to increase the Java Virtual Machine (JVM) memory allocated to Java services to improve performance in your Puppet Enterprise (PE) deployment.

- **Configuring ulimit for PE services** on page 171
  As your infrastructure grows and you bring more agents under management, you might need to increase the number allowed file handles per client.

- **Tuning standard installations** on page 172
  Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

- **Writing configuration files** on page 175
  Puppet supports two formats for configuration files that configure settings: valid JSON and Human-Optimized Config Object Notation (HOCON), a JSON superset.

- **Analytics data collection** on page 176
  Some components automatically collect data about how you use Puppet Enterprise. If you want to opt out of providing this data, you can do so, either during or after installing.

- **Static catalogs in Puppet Enterprise** on page 180
  A catalog is a document that describes the desired state for each resource that Puppet manages on a node. A master typically compiles a catalog from manifests of Puppet code. A static catalog is a specific type of Puppet catalog that includes metadata that specifies the desired state of any file resources containing source attributes pointing to puppet:///// locations on a node.
Methods for configuring Puppet Enterprise

After you’ve installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for `http` and `https` requests, or configure the number of JRuby instances.

PE shares configuration settings used in open source Puppet and documented in the Configuration Reference, however PE defaults for certain settings might differ from the Puppet defaults. Some examples of settings that have different PE defaults include `disable18n`, `environment_timeout`, `always_retry_plugins`, and the Puppet Server JRuby `max-active-instances` setting. To verify PE configuration defaults, check the `puppet.conf` file after installation.

There are three main methods for configuring PE: using the console, adding a key to Hiera, or editing `pe.conf`. Be consistent with the method you choose, unless the situation calls for you to use a specific method over the others.

**Important:** When you enable disaster recovery, you must use Hiera or `pe.conf` only — not the console — to specify configuration parameters. Using `pe.conf` or Hiera ensures that configuration is applied to both your master and replica.

**Related information**

- Configuring and tuning Puppet Server on page 153
  After you’ve installed Puppet Enterprise, optimize it for your environment by configuring and tuning Puppet Server settings as needed.
- Configuring and tuning PuppetDB on page 163
  After you’ve installed Puppet Enterprise, optimize it for your environment by configuring and tuning PuppetDB configuration as needed.
- Configuring and tuning the console on page 158
  After installing Puppet Enterprise, you can change product settings to customize the console's behavior, adjust to your team's needs, and improve performance. Many settings can be configured in the console itself.
- Configuring and tuning orchestration on page 165
  After installing PE, you can change some default settings to further configure the orchestrator and pe-orchestration-services.
- Configuring Java arguments on page 169
  You might need to increase the Java Virtual Machine (JVM) memory allocated to Java services to improve performance in your Puppet Enterprise (PE) deployment.

Configure settings using the console

The console allows you to use a graphical interface to configure Puppet Enterprise (PE).

Changes in the console will override your Hiera data and data in `pe.conf`. It is usually best to use the console when you want to:

- Change parameters in profile classes starting with `puppet_enterprise::profile`.
- Add any parameters in PE-managed configuration files.
- Set parameters that configure at runtime.

There are two ways to change settings in the console: setting configuration data and editing parameters.

**Related information**

- Preconfigured node groups on page 305
Puppet Enterprise includes preconfigured node groups that are used to manage your configuration.

**Set configuration data**
Configuration data set in the console is used for automatic parameter lookup, the same way that Hiera data is used. Console configuration data takes precedence over Hiera data, but you can combine data from both sources to configure nodes.

**Tip:** In most cases, setting configuration data in Hiera is the more scalable and consistent method, but there are some cases where the console is preferable. Use the console to set configuration data if:
- You want to override Hiera data. Data set in the console overrides Hiera data when configured as recommended.
- You want to give someone access to set or change data and they don’t have the skill set to do it in Hiera.
- You simply prefer the console user interface.

1. In the console, click **Node groups**, then find the node group that you want to add configuration data to and select it.
2. On the **Configuration data** tab, specify a **Class** and select a **Parameter** to add.
   - You can select from existing classes and parameters in the node group's environment, or you can specify free-form values. Classes aren’t validated, but any class you specify must be present in the node’s catalog at runtime in order for the parameter value to be applied.
   - When you select a parameter, the **Value** field is automatically populated with the inherited or default value.
3. Optional: Change the default parameter **Value**.

**Related information**
[Enable data editing in the console](#) on page 161

The ability to edit configuration data in the console is enabled by default in new installations. If you upgrade from an earlier version and didn't previously have configuration data enabled, you must manually enable classifier configuration data, because enabling requires edits to your **hiera.yaml** file.

**Set parameters**
Parameters are declared resource-style, which means they can be used to override other data; however, this override capability can introduce class conflicts and declaration errors that cause Puppet runs to fail.

1. In the console, click **Node groups**, and then find the node group that you want to add a parameter to and select it.
2. On the **Classes** tab, select the class you want to modify and the **Parameter** to add.
   - The **Parameter** drop-down list shows all of the parameters that are available for that class in the node group’s environment. When you select a parameter, the **Value** field is automatically populated with the inherited or default value.
3. (Optional) Change the default **Value**.

**Configure settings with Hiera**
Hiera is a hierarchy-based method of configuration management that relies on a “defaults, with overrides” system. When you add a parameter or setting to your Hiera data, Hiera searches through the data in the order it was written to find the value you want to change. Once found, it overrides the default value with the new parameter or setting. You can use Hiera to manage your PE configuration settings.

**Before you begin**
For more information on how to use Hiera, see the [Hiera docs](#).

Changes to PE configuration in Hiera will override configuration settings in **pe.conf**, but not those set in the console. It's best to use Hiera when you want to:
- Change parameters in non-profile classes.
- Set parameters that are static and version controlled.
- Configure for high availability.

To configure a setting using Hiera:
1. Open your default data file.
The default location for Hiera data files is:
   - *nix: /etc/puppetlabs/code/environments/<ENVIRONMENT>/data/common.yaml
   - Windows: %CommonAppData%\PuppetLabs\code\environments\<ENVIRONMENT>\data\common.yaml

   If you customize the hiera.yaml configuration to change location for data files (the datadir setting) or the path of the common data file (in the hierarchy section), look for the default .yaml file in the customized location.

2. Add your new parameter to the file in editor.
   For example, to increase the number of seconds before a node is considered unresponsive from the default 3600 to 4000, add the following to your .yaml default file and insert your new parameter at the end.

   Puppet_enterprise::console_services::no_longer_reporting_cutoff: 4000

3. To compile changes, run puppet agent -t

   Related information
   Preconfigured node groups on page 305
   Puppet Enterprise includes preconfigured node groups that are used to manage your configuration.

Configure settings in pe.conf

Puppet Enterprise (PE) configuration data includes any data set in /etc/puppetlabs/enterprise/conf.d/ but pe.conf is the file used for most configuration activities during installation.

PE configuration settings made in Hiera and the console always override settings made in pe.conf. Configure settings using pe.conf when you want to:
  - Access settings during installation.
  - Configure for high availability.

To configure settings using pe.conf:

1. Open the pe.conf file on your master:

   /etc/puppetlabs/enterprise/conf.d/pe.conf

2. Add the parameter and new value you want to set.
   For example, to change the proxy in your repo, add the following and change the parameter to your new proxy location.

   pe_repo::http_proxy_host: "proxy.example.vlan"

3. Run puppet agent -t
   Note: If PE services are stopped, run puppet infrastructure configure instead of puppet agent -t.

Configuring and tuning Puppet Server

After you’ve installed Puppet Enterprise, optimize it for your environment by configuring and tuning Puppet Server settings as needed.

Related information
Methods for configuring Puppet Enterprise on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

**Tuning standard installations** on page 172
Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

**Increase the Java heap size for PE Java services** on page 170
The Java heap size is the Java Virtual Machine (JVM) memory allocated to Java services in Puppet Enterprise (PE). You can use any configuration method you choose. We will use the console to change the Java heap size for console services, Puppet Server, orchestration services, or PuppetDB in the examples below.

**Configure ulimit for PE services** on page 171
The various services in PE require up to one file handle per connected client. On most operating system configurations, the defaults are not adequate for more than a couple hundred clients. To support more clients, you need to increase the number of allowed file handles.

### Tune the maximum number of JRuby instances
The `jruby_max_active_instances` setting controls the maximum number of JRuby instances to allow on the Puppet Server.

**Note:** This setting is referred to as `max_active_instances` without the `jruby` in front in the `pe-puppet-server.conf` file and in open source Puppet. It is the same setting.

The default used in PE is the number of CPUs - 1, expressed as `$::processorcount - 1`. One instance is the minimum value and four instances is the maximum value. Four JRuby instances works for most environments.

Because increasing the maximum number of JRuby instances also increases the amount of RAM used by `pe-puppetserver`, increase your heap size. We conservatively estimate that a JRuby process uses 512MB of RAM.

To change the number of instances using Hiera:

1. Add the following code to your default `.yaml` file and set the desired number of instances:

   ```yaml
   puppetenterprise::master::puppetserver::jruby_max_active_instances: <number of instances>
   ```

2. To compile the changes, run `puppet agent -t`

### Tune the maximum requests per JRuby instance
The `jruby_max_requests_per_instance` setting determines the maximum number of requests per instance of a JRuby interpreter before it is terminated.

**Note:** This setting is referred to as `max_requests_per_instance` without the `jruby` in front in the `pe-puppet-server.conf` file and in open source Puppet. It is the same setting.

The appropriate value for this parameter depends on how busy your servers are and how much you are affected by a memory leak. By default, `jruby_max_requests_per_instance` is set to 100,000 in PE.

When a JRuby interpreter is killed, all of its memory is reclaimed and it is replaced in the pool with a new interpreter. This prevents any one interpreter from consuming too much RAM, mitigating Puppet code memory leak issues and keeping Puppet Server up.

Starting a new interpreter has a performance cost, so set the parameter to get a new interpreter no more than every few hours. There are multiple interpreters running with requests balanced across them, so the lifespan of each interpreter varies.

To increase the maximum requests per instance using Hiera:
1. Add the following code to your default .yaml and set the desired number of requests.

   puppet_enterprise::master::puppetserver::jruby_max_requests_per_instance: <number of requests>

2. To compile the changes, run puppet agent -t

Tune the reserved_code_cache

The reserved_code_cache is an option for the Java Hotspot VM compiler. It sets the maximum amount of space available to store the compiler's code cache. Java limits the code cache size to 512mb minimum and 2048mb maximum.

JRuby requires an estimated 128mb of cache space per instance, so to determine the amount of space needed, calculate the number of JRuby instances x 128mb.

To adjust the reserved_code_cache, use Hiera or the console to change the parameter. For example, to change the cache size to 1024mb in the console, set the following parameter in the PE Master node group.

   puppet_enterprise::master::puppetserver::reserved_code_cache: 1024m

Tune the Ruby load path

The ruby_load_path setting determines where Puppet Server finds components such as Puppet and Facter.

The default setting is located at $puppetserver_jruby_puppet_ruby_load_path = ['/opt/puppetlabs/puppet/lib/ruby/vendor_ruby', '/opt/puppetlabs/puppet/cache/lib'].

Note: If you change the libdir you must also change the vardir.

To change the path to a different array in pe.conf:

1. Add the following to your pe.conf file on your master and set your new load path parameter.

   puppet_enterprise::master::puppetserver::puppetserver_jruby_puppet_ruby_load_path

2. Run puppet agent -t

Tune the multithreaded server setting

The jruby_puppet_multithreaded setting allows you to enable multithreaded mode, which uses a single JRuby instance to process requests, like catalog compiles, concurrently. The setting defaults to false.

To enable or disable the setting using Hiera:

1. Add the following code to your default .yaml file and set the parameter to true (enable) or false (disable). For example:

   puppet_enterprise::master::puppetserver::jruby_puppet_multithreaded: <true or false>

2. To compile the changes, run puppet agent -t

Enable or disable cached data when updating classes

The optional environment-class-cache-enabled setting specifies whether cached data is used when updating classes in the console. When true, Puppet Server refreshes classes using file sync, improving performance.

The default value for environment-class-cache-enabled depends on whether you use Code Manager.

- With Code Manager, the default value is enabled (true). File sync clears the cache automatically in the background, so clearing the environment cache manually isn't required when using Code Manager.
- Without Code Manager, the default value is disabled (false).
**Note:** If you're not using Code Manager and opt to enable this setting, make sure your code deployment method — for example r10k — clears the environment cache when it completes. If you don't clear the environment cache, the Node Classifier doesn't receive new class information until Puppet Server is restarted.

To enable or disable the cache using Hiera:

1. Add the following code to your default `.yaml` file and set the parameter to the appropriate setting.

   ```yaml
   puppet_enterprise::master::puppetserver::
   jruby_environment_class_cache_enabled: <true OR false>
   ``

2. To compile the changes, run `puppet agent -t`

**Change the environment_timeout setting**

The `environment_timeout` setting controls how long the master caches data it loads from an environment, determining how much time passes before changes to an environment's Puppet code are reflected in its environment.

In PE, the `environment_timeout` is set to 0. This lowers the performance of your master but makes it easy for new users to deploy updated Puppet code. Once your code deployment process is mature, change this setting to unlimited.

**Note:** When you install Code Manager and set the `code_manager_auto_configure` parameter to `true`, `environment_timeout` is updated to `unlimited`

To change the `environment_timeout` setting using `pe.conf`:

1. Add the following to your `pe.conf` file on your master and specify either 0 or unlimited:

   ```yaml
   puppet_enterprise::pe.conf file on your master and specify either 0 or unlimited:
   puppet_enterprise::master::environment_timeout:<time>
   ``

2. Run `puppet agent -t`

For more information, see Environments limitations

**Add certificates to the puppet-admin certificate whitelist**

Add trusted certificates to the puppet-admin certificate whitelist.

To add certificates to the whitelist using `pe.conf`:

1. Add the following code to your `pe.conf` file on your master and add the desired certificates.

   ```yaml
   puppet_enterprise::master::puppetserver::puppet_admin_certs:'example_cert_name'
   ``

2. Run `puppet agent -t`

**Disable update checking**

Puppet Server (`pe-puppetserver`) checks for updates when it starts or restarts, and every 24 hours thereafter. It transmits basic, anonymous info to our servers at Puppet, Inc. to get update information. You can optionally turn this off.

Specifically, it transmits:

- Product name
- Puppet Server version
- IP address
- Data collection timestamp

To turn off update checking using the console:

1. Open the console, click Node groups, and select the PE Master node group.
2. On the Classes tab, find the `puppet_enterprise::profile::master` class, add the `check_for_updates` parameter from the list, and change its value to `false`.

© 2020 Puppet, Inc.
3. Click **Add parameter** and commit changes.
4. On the nodes hosting the master and console, run Puppet.

**Puppet Server configuration files**

At startup, Puppet Server reads all of the `.conf` files in the `conf.d` directory (`/etc/puppetlabs/puppetserver/conf.d`).

The `conf.d` directory contains the following files:

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth.conf</td>
<td>Contains authentication rules and settings for agents and API endpoint access.</td>
</tr>
<tr>
<td>global.conf</td>
<td>Contains global configuration settings for Puppet Server, including logging settings.</td>
</tr>
<tr>
<td>metrics.conf</td>
<td>Contains settings for Puppet Server metrics services.</td>
</tr>
<tr>
<td>pe-puppet-server.conf</td>
<td>Contains Puppet Server settings specific to Puppet Enterprise.</td>
</tr>
<tr>
<td>webserver.conf</td>
<td>Contains SSL service configuration settings.</td>
</tr>
<tr>
<td>ca.conf</td>
<td>(Deprecated) Contains rules for Certificate Authority services. Superseded by <code>webserver.conf</code> and <code>auth.conf</code>.</td>
</tr>
</tbody>
</table>

For information about Puppet Server configuration files, see [Puppet Server's config files](#) for the Puppet Server version you're using, and the Related information links below.

**Related information**

Viewing and managing Puppet Server metrics on page 266

Puppet Server can provide performance and status metrics to external services for monitoring server health and performance over time.

**pe-puppet-server.conf settings**

The `pe-puppet-server.conf` file contains Puppet Server settings specific to Puppet Enterprise, with all settings wrapped in a `jruby-puppet` section.

- **gen-home**
  
  Determines where JRuby looks for gems. It is also used by the `puppetserver gem` command line tool.
  
  Default: `/opt/puppetlabs/puppet/cache/jruby-gems`

- **master-conf-dir**
  
  Sets the Puppet configuration directory's path.
  
  Default: `/etc/puppetlabs/puppet`

- **master-var-dir**
  
  Sets the Puppet variable directory's path.
  
  Default: `/opt/puppetlabs/server/data/puppetserver`

- **max-queued-requests**
  
  Optional. Sets the maximum number of requests that can be queued waiting to borrow a from the pool. After this limit is exceeded, a 503 Service Unavailable response is returned for all new requests until the queue drops below the limit.
  
  If `max-retry-delay` is set to a positive value, then the 503 response includes a Retry-After header indicating a random sleep time after which the client can retry the request.
Note: Don’t use this solution if your managed infrastructure includes a significant number of agents older than Puppet 5.3. Older agents treat a 503 response as a failure, which ends their runs, causing groups of older agents to schedule their next runs at the same time, creating a thundering herd problem.

Default: 0

max-retry-delay
Optional. Sets the upper limit in seconds for the random sleep set as a Retry-After header on 503 responses returned when max-queued-requests is enabled.
Default: 1800

jruby_max_active_instances
Controls the maximum number of JRuby instances to allow on the Puppet Server.
Default: 4

max_requests_per_instance
Sets the maximum number of requests per instance of a JRuby interpreter before it is killed.
Default: 100000

ruby-load-path
Sets the Puppet configuration directory's path. The agent's libdir value is added by default.
Default: '/opt/puppetlabs/puppet/lib/ruby/vendor_ruby', '/opt/puppetlabs/puppet_cache/lib'

Configuring and tuning the console
After installing Puppet Enterprise, you can change product settings to customize the console's behavior, adjust to your team’s needs, and improve performance. Many settings can be configured in the console itself.

Related information
Methods for configuring Puppet Enterprise on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

Disable update checking on page 156
Puppet Server (pe-puppetserver) checks for updates when it starts or restarts, and every 24 hours thereafter. It transmits basic, anonymous info to our servers at Puppet, Inc. to get update information. You can optionally turn this off.

Configuring Java arguments on page 169
You might need to increase the Java Virtual Machine (JVM) memory allocated to Java services to improve performance in your Puppet Enterprise (PE) deployment.

Configure ulimit for PE services on page 171
The various services in PE require up to one file handle per connected client. On most operating system configurations, the defaults are not adequate for more than a couple hundred clients. To support more clients, you need to increase the number of allowed file handles.

Configure the PE console and console-services
Configure the behavior of the console and console-services, as needed.

Note: Use the Hiera or pe.conf method to configure non-profile classes, such as puppet_enterprise::api_port and puppet_enterprise::console_services::no_longer_reporting_cutoff.

To configure settings in the console:
1. Click Node groups, and select the node group that contains the class you want to work with.
2. On the **Classes** tab, find the class you want to work with, select the **Parameter name** from the list and edit its value.

3. Click **Add parameter** and commit changes.

4. On the nodes hosting the master and console, run Puppet.

**Related information**

[Running Puppet on nodes](#) on page 294

Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

**Console and console-services parameters**

Use these parameters to customize the behavior of the console and console-services. Parameters that begin with `puppet_enterprise::profile` can be modified from the console itself. See the configuration methods documents for more information on how to change parameters in the console or Hiera.

- **puppet_enterprise::profile::console::classifier_synchronization_period**
  
  Integer representing, in seconds, the classifier synchronization period, which controls how long it takes the node classifier to retrieve classes from the master.

  Default: "600" (seconds).

- **puppet_enterprise::profile::console::rbac_failed_attempts_lockout**
  
  Integer specifying how many failed login attempts are allowed on an account before that account is revoked.

  Default: "10" (attempts).

- **puppet_enterprise::profile::console::rbac_password_reset_expiration**
  
  Integer representing, in hours, how long a user's generated token is valid for. An administrator generates this token for a user so that they can reset their password.

  Default: "24" (hours).

- **puppet_enterprise::profile::console::rbac_session_timeout**
  
  Integer representing, in minutes, how long a user's session can last. The session length is the same for node classification, RBAC, and the console.

  Default: "60" (minutes).

- **puppet_enterprise::profile::console::session_maximum_lifetime**
  
  Integer representing the maximum allowable period that a console session can be valid. To not expire before the maximum token lifetime, set to '0'.

  Supported units are "s" (seconds), "m" (minutes), "h" (hours), "d" (days), "y" (years). Units are specified as a single letter following an integer, for example "1d"(1 day). If no units are specified, the integer is treated as seconds.

- **puppet_enterprise::profile::console::console_ssl_listen_port**
  
  Integer representing the port that the console is available on.

  Default: [443]

- **puppet_enterprise::profile::console::ssl_listen_address**
  
  Nginx listen address for the console.

  Default: "0.0.0.0"

- **puppet_enterprise::profile::console::classifier_prune_threshold**
  
  Integer representing the number of days to wait before pruning the size of the classifier database. If you set the value to "0", the node classifier service is never pruned.

- **puppet_enterprise::profile::console::classifier_node_check_in_storage**
  
  "true" to store an explanation of how nodes match each group they're classified into, or "false".
Default: "false"

**puppet Enterprise::profile::console::display_local_time**

"true" to display timestamps in local time, with hover text showing UTC time, or "false" to show timestamps in UTC time.

Default: "false"

Modify these configuration parameters in Hiera or `pe.conf`, not the console:

**puppet Enterprise::api_port**

SSL port that the node classifier is served on.

Default: [4433]

**puppet Enterprise::console_services::no_longer_reporting_cutoff**

Length of time, in seconds, before a node is considered unresponsive.

Default: 3600 (seconds)

**console_admin_password**

The password to log into the console, for example "myconsolepassword".

Default: Specified during installation.

### Manage the HTTPS redirect

By default, the console redirects to HTTPS when you attempt to connect over HTTP. You can customize the redirect target URL or disable redirection.

#### Customize the HTTPS redirect target URL

By default, the redirect target URL is the same as the FQDN of your master, but you can customize this redirect URL.

To change the target URL in the console:

1. Click **Node groups**, and select the **PE Infrastructure** node group.
2. On the **Classes** tab, find the `puppet Enterprise::profile::console::proxy::http_redirect` class, select the `server_name` parameter from the list, and change its value to the desired server.
3. Click **Add parameter** and commit changes.
4. On the nodes hosting the master and console, run Puppet.

#### Disable the HTTPS redirect

The pe-nginx webserver listens on port 80 by default. If you need to run your own service on port 80, you can disable the HTTPS redirect.

1. Add the following to your default `.yaml` file with the parameter set to `false`.

   ```
   puppet Enterprise::profile::console::proxy::http_redirect::enable_http_redirect: false
   ```

2. To compile changes, run `puppet agent -t` on the master.

### Tuning the PostgreSQL buffer pool size

If you are experiencing performance issues or instability with the console, adjust the buffer memory settings for PostgreSQL.

The most important PostgreSQL memory settings for PE are `shared_buffers` and `work_mem`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>shared_buffers</code></td>
<td>in MB. Set at about 25 percent of your hardware's RAM.</td>
</tr>
</tbody>
</table>
To change the PostgreSQL memory settings using the console:

1. Click **Node groups**, and in the **PE Infrastructure** group, select **PE Database** group.
2. On the **Classes** tab, find the **shared_buffers** and **work_mem** parameters from the drop down and edit their values as desired.
3. Click **Add parameter** and commit changes.
4. On the nodes hosting the master and console, run **Puppet**.
5. Restart the PostgreSQL server: `sudo /etc/init.d/pe-postgresql restart`

### Enable data editing in the console

The ability to edit configuration data in the console is enabled by default in new installations. If you upgrade from an earlier version and didn't previously have configuration data enabled, you must manually enable classifier configuration data, because enabling requires edits to your `hiera.yaml` file.

1. On your master, edit `/etc/puppetlabs/puppet/hiera.yaml` to add:

   ```yaml
   hierarchy:
     - name: "Classifier Configuration Data"
       data_hash: classifier_data
   
   Place any additional hierarchy entries, such as `hiera-yaml` or `hiera-eyaml` under the same hierarchy key, preferably below the **Classifier Configuration Data** entry.

   **Note:** If you enable data editing in the console, add both **Set environment** and **Edit configuration data** to groups that set environment or modify class parameters in order for users to make changes.

2. If your environment is configured for disaster recovery, update `hiera.yaml` on your replica.

### Add custom PQL queries to the console

Add your own PQL queries to the console and quickly access them when running jobs.

1. On your Master, as root, copy the `custom_pql_queries.json.example` file and remove the example suffix.

   ```bash
   cp /etc/puppetlabs/console-services/custom_pql_queries.json.example /etc/puppetlabs/console-services/custom_pql_queries.json
   
   2. Edit the file contents to include your own PQL queries or remove any existing queries.

   3. Refresh the console UI in your browser.

   You can now see your custom queries in the PQL drop down options when running jobs.

---

**Configuring and tuning security settings**

Ensure your PE environment is secure by configuring security settings.
• **Configure cipher suites** on page 162
  Due to regulatory compliance or other security requirements, you may need to change which cipher suites your SSL-enabled PE services use to communicate with other PE components.

• **Configure SSL protocols** on page 162
  Add or remove SSL protocols in your PE infrastructure.

• **Configure RBAC and token-based authentication settings** on page 163
  Tune RBAC and token-based authentication settings, like setting the number of failed attempts a user has before they are locked out of the console or changing the amount of time a token is valid for.

### Configure cipher suites
Due to regulatory compliance or other security requirements, you may need to change which cipher suites your SSL-enabled PE services use to communicate with other PE components.

#### SSL ciphers for core Puppet services
To add or remove cipher suites for core Puppet services, use Hiera to add an array of SSL ciphers to the `puppetenterprise::ssl_cipher_suites` parameter.

**Note:** Changing this parameter overrides the default list of SSL cipher suites.

The example Hiera data below replaces the default list of cipher suites to only allow the four specified.

```yaml
puppet-enterprise::ssl_cipher_suites:
  - 'SSL_RSA_WITH_NULL_MD5'
  - 'SSL_RSA_WITH_NULL_SHA'
  - 'TLS_DH_anon_WITH_AES_128_CBC_SHA'
  - 'TLS_DH_anon_WITH_AES_128_CBC_SHA256'
```

**Note:** Cipher names are in IANA RFC naming format.

#### SSL for console services
To add or remove cipher suites for console services affecting traffic on port 443, use Hiera or the console to change the `puppetenterprise::profile::console::proxy::ssl_ciphers` parameter.

For example, to change the parameter in the console, in the PE Console node group, add an array of SSL ciphers to the `ssl_ciphers` parameter in the `puppet-enterprise::profile::console::proxy` class.

### Configure SSL protocols
Add or remove SSL protocols in your PE infrastructure.

To change what SSL protocols your PE infrastructure uses, use Hiera or the console to add or remove protocols.

Use the parameter `puppet-enterprise::master::puppetserver::ssl_protocols` and add an array for protocols you want to include, or remove protocols you no longer want to use.

For example, to enable TLSv1.1 and TLSv1.2, set the following parameter in the PE Infrastructure group in the console or in your Hiera data.

```yaml
puppet-enterprise::master::puppetserver::ssl_protocols["TLSv1.1", "TLSv1.2"]
```

**Note:** To comply with security regulations, PE 2019.1 and later uses only version 1.2 of the Transport Layer Security (TLS) protocol.
Configure RBAC and token-based authentication settings

Tune RBAC and token-based authentication settings, like setting the number of failed attempts a user has before they are locked out of the console or changing the amount of time a token is valid for.

RBAC and token authentication settings can be changed in the PE Infrastructure group in the console or in your Hiera data. Below is a list of related settings.

- **puppet_enterprise::profile::console::rbac_failed_attempts_lockout**
  - An integer specifying how many failed login attempts are allowed on an account before the account is revoked. The default is "10" (attempts).

- **puppet_enterprise::profile::console::rbac_password_reset_expiration**
  - An integer representing, in hours, how long a user's generated token is valid for. An administrator generates this token for a user to that they can reset their password. The default is "24" (hours).

- **puppet_enterprise::profile::console::rbac_session_timeout**
  - Integer representing, in minutes, how long a user's session can last. The session length is the same for node classification, RBAC, and the console. The default is "60" (minutes).

- **puppet_enterprise::profile::console::rbac_token_auth_lifetime**
  - A value representing the default authentication lifetime for a token. It cannot exceed the rbac_token_maximum_lifetime. This is represented as a numeric value followed by "y" (years), "d" (days), "h" (hours), "m" (minutes), or "s" (seconds). The default is "1h".

- **puppet_enterprise::profile::console::rbac_token_maximum_lifetime**
  - A value representing the maximum allowable lifetime for all tokens. This is represented as a numeric value followed by "y" (years), "d" (days), "h" (hours), "m" (minutes), or "s" (seconds). The default is "10y".

- **puppet_enterprise::profile::console::rbac_account_expiry_check_minutes**
  - An integer that specifies, in minutes, how often the application checks for idle user accounts. The default value is "60" (minutes).

- **puppet_enterprise::profile::console::rbac_account_expiry_days**
  - An integer that specifies, in days, the duration before an inactive user account expires. The default is undefined. To activate the feature, add a value of "1" or greater.

  If a non-superuser hasn't logged into the console during this specified period, their user status updates to revoked. After creating an account, if a non-superuser hasn't logged in to the console during the specified period, their user status updates to revoked.

  **Note:** If you do not specify the rbac_account_expiry_days parameter, the rbac_account_expiry_check_minutes parameter is ignored.

Configuring and tuning PuppetDB

After you've installed Puppet Enterprise, optimize it for your environment by configuring and tuning PuppetDB configuration as needed.

This page covers a few key topics, but additional settings and information about configuring PuppetDB is available in the PuppetDB configuration documentation. Be sure to check that the PuppetDB docs version you're looking at matches the one version of PuppetDB in your PE.

**Related information**

- **Methods for configuring Puppet Enterprise** on page 151
  After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

- **Tuning standard installations** on page 172

© 2020 Puppet, Inc.
Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

**Configure settings with Hiera** on page 152

Hiera is a hierarchy-based method of configuration management that relies on a “defaults, with overrides” system. When you add a parameter or setting to your Hiera data, Hiera searches through the data in the order it was written to find the value you want to change. Once found, it overrides the default value with the new parameter or setting. You can use Hiera to manage your PE configuration settings.

**Configure ulimit for PE services** on page 171

The various services in PE require up to one file handle per connected client. On most operating system configurations, the defaults are not adequate for more than a couple hundred clients. To support more clients, you need to increase the number of allowed file handles.

**Increase the Java heap size for PE Java services** on page 170

The Java heap size is the Java Virtual Machine (JVM) memory allocated to Java services in Puppet Enterprise (PE). You can use any configuration method you choose. We will use the console to change the Java heap size for console services, Puppet Server, orchestration services, or PuppetDB in the examples below.

**Configure agent run reports**

By default, every time Puppet runs, the master generates agent run reports and submits them to PuppetDB. You can enable or disable this as needed.

To enable or disable agent run reports using the console:

1. Click **Node groups**, and in the **PE Infrastructure** group, select the **PE Master** group.
2. On the **Classes** tab, add the puppet_enterprise::profile::master::puppetdb class, select the report_processor_ensure parameter, and enter the value present to enable agent run reports or absent to disable agent run reports.
3. Click **Add parameter** and commit changes.
4. On the nodes hosting the master and console, run Puppet.

**Configure command processing threads**

The `command_processing_threads` setting defines how many command processing threads PuppetDB uses to sort incoming data. Each thread can process a single command at a time. The setting defaults to half the number of cores in your system.

To set the number of threads using `pe.conf`:

1. Add the following code to your `pe.conf` file on your master and set your new parameter.

   ```
puppet_enterprise::puppetdb::command_processing_threads: <number of threads>
   ```

2. Run `puppet agent -t`

**Configure how long before PE stops managing deactivated nodes**

Use the `node-purge-ttl` parameter to set the "length of time" value before PE automatically removes nodes that have been deactivated or expired. This also removes all facts, catalogs, and reports for the relevant nodes.

To change the amount of time before nodes are purged using the console:

1. Click **Node groups**, and in the PE Infrastructure group, select the **PE Database** group.
2. On the **Classes** tab, find the `puppet_enterprise::profile::puppetdb` class, find the `node_purge_ttl` parameter, and change its value to the desired amount of time.

To change the unit of time, use the following suffixes:

- **d** - days
- **h** - hours
- **m** - minutes
- **s** - seconds
- **ms** - milliseconds

For example, to set the purge time to 14 days:

```
puppet_enterprise::profile::puppetdb::node_purge_ttl: '14d'
```

3. Click **Add parameter** and commit changes.

4. On the nodes hosting the master and console, run Puppet.

**Change the PuppetDB user password**

The console uses a database user account to access its PostgreSQL database. Change it if it is compromised or to comply with security guidelines.

To change the password:

1. Stop the `pe-puppetdb` puppet service by running `puppet resource service pe-puppetdb ensure=stopped`

2. On the database server (which might or might not be the same as PuppetDB, depending on your deployment's architecture), use the PostgreSQL administration tool of your choice to change the user's password. With the standard PostgreSQL client, you can do this by running `ALTER USER console PASSWORD '<new password>';`

3. Edit `/etc/puppetlabs/puppetdb/conf.d/database.ini` on the PuppetDB server and change the password: line under `common` or `production`, depending on your configuration, to contain the new password.

4. Start the `pe-puppetdb` service on the console server by running `puppet resource service pe-puppetdb ensure=running`

**Configure excluded facts**

Use the `facts_blacklist` parameter exclude facts from being stored in the PuppetDB database.

To specify which facts you want to exclude using Hiera:

1. Add the following to your default `.yaml` file and list the facts you want to exclude. For example, to exclude the facts `system_uptime_example` and `mountpoints_example`:

```
puppet_enterprise::puppetdb::database_ini::facts_blacklist:
- 'system_uptime_example'
- 'mountpoints_example'
```

2. To compile changes, run `puppet agent -t`

**Configuring and tuning orchestration**

After installing PE, you can change some default settings to further configure the orchestrator and pe-orchestration-services.

**Related information**

- [Methods for configuring Puppet Enterprise](#) on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

**Tuning standard installations** on page 172
Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

**Configure ulimit for PE services** on page 171
The various services in PE require up to one file handle per connected client. On most operating system configurations, the defaults are not adequate for more than a couple hundred clients. To support more clients, you need to increase the number of allowed file handles.

### Configure the orchestrator and pe-orchestration-services

There are several optional parameters you can add to configure the behavior of the orchestrator and pe-orchestration-services. Because they are profile classes, you can change these in the console in the PE Orchestrator group.

**puppet_enterprise::profile::orchestrator::task_concurrency**

Integer representing the number of simultaneous task or plan actions that can run at the same time in the orchestrator. All task and plan actions are limited by this concurrency limit regardless of transport type (WinRM, SSH, PCP).

Default: "250" (actions)

**puppet_enterprise::profile::bolt_server::concurrency**

An integer that determines the maximum number of simultaneous task or plan requests orchestrator can make to bolt-server. Only task or plan executions on nodes with SSH or WinRM transport methods are limited by this setting because only they require requests to bolt-server.

Default: "100" (requests)

⚠️ **CAUTION:** Do not set a concurrency limit that is higher than the bolt-server limit. This can cause timeouts that lead to failed task runs.

**puppet_enterprise::profile::agent::pxp_enabled**

Disable or enable the PXP service by setting it to true or false. If you disable this setting you can’t use the orchestrator or the Run Puppet button in the console.

Default: true

**puppet_enterprise::profile::orchestrator::global_concurrent_compiles**

An integer that determines how many concurrent compile requests can be outstanding to the master, across all orchestrator jobs.

Default: "8" (requests)

**puppet_enterprise::profile::orchestrator::job_prune_threshold**

Integer that represents the number of days before job reports are removed.

Default: "30" (days)

**puppet_enterprise::profile::orchestrator::pcp_timeout**

An integer that represents how many seconds must pass while an agent attempts to connect to a PCP broker. If the agent can’t connect to the broker in that time frame, the run times out.

Default: "30" (seconds)

**puppet_enterprise::profile::orchestrator::run_service**

Disable or enable orchestration services. Set to true or false.

Default: true
puppet_enterprise::profile::orchestrator::use_application_services

Enable or disable application management. Set to `true` or `false`.

Default: `false`

Related information

Running Puppet on nodes on page 294

Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

Configure the PXP agent

Puppet Execution Protocol (PXP) is a messaging system used to request tasks and communicate task statuses. The PXP agent runs the PXP service and you can configure it using Hiera.

puppet_enterprise::pxp_agent::ping_interval

Controls how frequently (in seconds) PXP agents will ping PCP brokers. If the brokers don’t respond, the agents try to reconnect.

Default: 120 (seconds)

puppet_enterprise::pxp_agent::pxp_logfile

A string that represents the path to the PXP agent log file and can be used to debug issues with orchestrator.

Default:
- *nix: `/var/log/puppetlabs/pxp-agent/pxp-agent.log`
- Windows: `C:\Program Data\PuppetLabs\pxp-agent\var\log\pxp-agent.log`

puppet_enterprise::pxp_agent::spool_dir_purge_ttl

The amount of time to keep records of old Puppet or task runs on agents. You can declare time in minutes (30m), hours (2h), and days (14d).

Default: 14d

puppet_enterprise::pxp_agent::task_cache_dir_purge_ttl

Controls how long tasks are cached after use. You can declare time in minutes (30m), hours (2h), and days (14d).

Default: 14d

Correct ARP table overflow

In larger deployments that use the PCP broker, you might encounter ARP table overflows and need to adjust some system settings.

Overflows occur when the ARP table—a local cache of IP address to MAC address resolutions—fills and starts evicting old entries. When frequently used entries are evicted, network traffic will increase to restore them, increasing network latency and CPU load on the broker.

A typical log message looks like:

```
[root@s1 peadmin]# tail -f /var/log/messages
Aug 10 22:42:36 s1 kernel: Neighbour table overflow.
Aug 10 22:42:36 s1 kernel: Neighbour table overflow.
Aug 10 22:42:36 s1 kernel: Neighbour table overflow.
```

To work around this issue:

Increase sysctl settings related to ARP tables.

For example, the following settings are appropriate for networks hosting up to 2000 agents:

```
# Set max table size
net.ipv6.neigh.default.gc_thresh3=4096
```
Configuring proxies

You can work around limited internet access by configuring proxies at various points in your infrastructure, depending on your connectivity limitations.

The examples provided here assume an unauthenticated proxy running at proxy.example.vlan on port 8080.

**Related information**

- [Methods for configuring Puppet Enterprise](#) on page 151

After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

### Downloading agent installation packages through a proxy

If your master doesn't have internet access, it can't download agent installation packages. If you want to use package management to install agents, set up a proxy and specify its connection details so that `pe_repo` can access agent tarballs.

In the `pe_repo` class of the **PE Master** node group, specify values for `pe_repo::http_proxy_host` and `pe_repo::http_proxy_port` settings.

If you want to specify these settings in `pe.conf`, add the following to your `pe.conf` file with your desired parameters:

```
"pe_repo::http_proxy_host": "proxy.example.vlan",
"pe_repo::http_proxy_port": 8080
```

**Tip:** To test proxy connections to `pe_repo`, run:

**Bash**

```bash
proxy_uri='http://proxy.example.vlan:8080'
uri='https://pm.puppetlabs.com'

curl --proxy "$proxy_uri" --head "$uri"
```

### Setting a proxy for agent traffic

General proxy settings in `puppet.conf` manage HTTP connections that are directly initiated by the agent.

To configure agents to communicate through a proxy using `pe.conf`, specify values for the `http_proxy_host` and `http_proxy_port` settings in `/etc/puppetlabs/puppet/puppet.conf`.

```
http_proxy_host = proxy.example.vlan
http_proxy_port = 8080
```

For more information about HTTP proxy host options, see the Puppet [configuration reference](#).

```
Setting a proxy for Code Manager traffic

Code Manager has its own set of proxy configuration options which you can use to set a proxy for connections to the Git server or the Forge. These settings are unaffected by the proxy settings in puppet.conf, because Code Manager is run by Puppet Server.

Note: To set a proxy for Code Manager connections, you must use an HTTP URL for your r10k remote and for all Puppetfile module entries.

Use a proxy for all HTTP connections, including both Git and the Forge, when configuring Code Manager.

To configure Code Manager to use a proxy using Hiera, add the following code to your default .yaml and specify your proxy name. For example:

```
puppet_enterprise::profile::master::r10k_proxy: "http://proxy.example.vlan:8080"
```

Tip: To test proxy connections to Git or the Forge, run one of these commands:

Bash

```
proxy_uri='http://proxy.example.vlan:8080'
uri='https://github.com'
curl --proxy "$proxy_uri" --head "$uri"
```

Bash

```
proxy_uri='http://proxy.example.vlan:8080'
uri='https://forgeapi.puppet.com'
curl --proxy "$proxy_uri" --head "$uri"
```

For detailed information about configuring proxies for Code Manager traffic, see the Code Manager documentation.

Related information

Configuring proxies on page 597

To configure proxy servers, use the proxy setting. You can set a global proxy for all HTTP(S) operations, for all Git or Forge operations, or for a specific Git repository only.

Configuring Java arguments

You might need to increase the Java Virtual Machine (JVM) memory allocated to Java services to improve performance in your Puppet Enterprise (PE) deployment.

Important: When you enable disaster recovery, you must use Hiera or pe.conf only — not the console — to specify configuration parameters. Using pe.conf or Hiera ensures that configuration is applied to both your master and replica.

Related information

Methods for configuring Puppet Enterprise on page 151

After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

Tuning standard installations on page 172
Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

**Increase the Java heap size for PE Java services**

The Java heap size is the Java Virtual Machine (JVM) memory allocated to Java services in Puppet Enterprise (PE). You can use any configuration method you choose. We will use the console to change the Java heap size for console services, Puppet Server, orchestration services, or PuppetDB in the examples below.

**Note:** Ensure that you have sufficient free memory before increasing the memory that is used by a service. The increases shown below are only examples.

1. In the console, click **Node groups.** In the **PE Infrastructure** node group, select the node group that corresponds to the service you're increasing heap size for.

<table>
<thead>
<tr>
<th>Service</th>
<th>Node group</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-console-services</td>
<td>PE Console</td>
</tr>
<tr>
<td>Puppet Server</td>
<td>PE Master</td>
</tr>
<tr>
<td>pe-orchestration-services</td>
<td>PE Orchestrator</td>
</tr>
<tr>
<td>PuppetDB</td>
<td>PE PuppetDB</td>
</tr>
<tr>
<td>ActiveMQ</td>
<td>PE ActiveMQ Broker</td>
</tr>
</tbody>
</table>

2. Click **Classes** and scroll down to the appropriate class.

<table>
<thead>
<tr>
<th>Node group</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>PE Console</td>
<td>puppet_enterprise::profile::console</td>
</tr>
<tr>
<td>PE Master</td>
<td>puppet_enterprise::profile::master</td>
</tr>
<tr>
<td>PE Orchestrator</td>
<td>puppet_enterprise::profile::orchestrator</td>
</tr>
<tr>
<td>PE PuppetDB</td>
<td>puppet_enterprise::profile::puppetdb</td>
</tr>
<tr>
<td>PE ActiveMQ Broker</td>
<td>puppet_enterprise::profile::amq::broker</td>
</tr>
</tbody>
</table>

3. Click the **Parameter name** list and select **java_args.** Increase the heap size by replacing the parameter with the appropriate JSON string.

<table>
<thead>
<tr>
<th>Service</th>
<th>Default heap size</th>
<th>New heap size</th>
<th>JSON string</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-console-services</td>
<td>256 MB</td>
<td>512 MB</td>
<td>{&quot;Xmx&quot;: &quot;512m&quot;, &quot;Xms&quot;: &quot;512m&quot;}</td>
</tr>
<tr>
<td>Puppet Server</td>
<td>2 GB</td>
<td>4 GB</td>
<td>{&quot;Xmx&quot;: &quot;4096m&quot;, &quot;Xms&quot;: &quot;4096m&quot;}</td>
</tr>
<tr>
<td>orchestration-services</td>
<td>192 MB</td>
<td>1000 MB</td>
<td>{&quot;Xmx&quot;: &quot;1000m&quot;, &quot;Xms&quot;: &quot;1000m&quot;}</td>
</tr>
<tr>
<td>PuppetDB</td>
<td>256 MB</td>
<td>512 MB</td>
<td>{&quot;Xmx&quot;: &quot;512m&quot;, &quot;Xms&quot;: &quot;512m&quot;}</td>
</tr>
<tr>
<td>ActiveMQ</td>
<td>512 MB</td>
<td>1024 MB</td>
<td>{&quot;Xmx&quot;: &quot;1024m&quot;, &quot;Xms&quot;: &quot;1024m&quot;}</td>
</tr>
</tbody>
</table>

4. Click **Add Parameter** and then commit changes.
5. Run Puppet on the appropriate nodes to apply the change. If you're running it on the console node, the console will be unavailable briefly while `pe-console-services` restarts.

<table>
<thead>
<tr>
<th>Service</th>
<th>Node</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-console-services</td>
<td>console</td>
</tr>
<tr>
<td>Puppet Server</td>

</tr>
<tr>
<td>pe-orchestration-services</td>
<td>master</td>
</tr>
<tr>
<td>PuppetDB</td>
<td>PuppetDB</td>
</tr>
</tbody>
</table>

Related information

Running Puppet on nodes on page 294
Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

Disable Java garbage collection logging

Java garbage collection logs can be useful when diagnosing performance issues with JVM-based PE services. Garbage collection logs are enabled by default, and the results are captured in the support script, but you can disable them.

Use Hiera or `pe.conf` to disable garbage collection logging by adding or changing the following parameters, as needed:

```plaintext
puppet_enterprise::console_services::enable_gc_logging: false
puppet_enterprise::master::puppetserver::enable_gc_logging: false
puppet_enterprise::profile::orchestrator::enable_gc_logging: false
puppet_enterprise::puppetdb::enable_gc_logging: false
puppet_enterprise::profile::amq::broker::enable_gc_logging: false
```

Configuring ulimit for PE services

As your infrastructure grows and you bring more agents under management, you might need to increase the number allowed file handles per client.

Related information

Methods for configuring Puppet Enterprise on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for `http` and `https` requests, or configure the number of JRuby instances.

Configure ulimit for PE services

The various services in PE require up to one file handle per connected client. On most operating system configurations, the defaults are not adequate for more than a couple hundred clients. To support more clients, you need to increase the number of allowed file handles.

You can increase the limits for the following services:

- `pe-orchestration-services`
- `pe-puppetdb`
- `pe-console-services`
- `pe-puppetserver`
- `pe-puppet`

The location and method for configuring ulimit depends on your agent’s platform. You might use systemd, upstart, or some other init system.
In the following instructions, replace `<PE SERVICE>` with the specific service you’re editing. The examples show setting a limit of 32768, which you can also change according to what you need.

**Configure ulimit using systemd**

With systemd, the number of open file handles allowed is controlled by a setting in the service file at `/usr/lib/systemd/system/<PE SERVICE>.service`.

1. To increase the limit, run the following commands, setting the `LimitNOFILE` value to the new number:

   ```bash
   mkdir /etc/systemd/system/<PE SERVICE>.service.d
   echo "[Service] LimitNOFILE=32768" > /etc/systemd/system/<PE SERVICE>.service.d/limits.conf
   systemctl daemon-reload
   ```

2. Confirm the change by running:

   ```bash
   systemctl show <PE SERVICE> | grep LimitNOFILE
   ```

**Configure ulimit using upstart**

For Ubuntu and Red Hat systems, the number of open file handles allowed for is controlled by settings in service files.

The service files are:

- Ubuntu: `/etc/default/<PE SERVICE>`
- Red Hat: `/etc/sysconfig/<PE SERVICE>`

For both Ubuntu and Red Hat, set the last line of the file as follows:

```bash
ulimit -n 32678
```

This sets the number of open files allowed at 32,678.

**Configure ulimit on other init systems**

The ulimit controls the number of processes and file handles that the PE service user can open and process.

To increase the ulimit for a PE service user:

Edit `/etc/security/limits.conf` so that it contains the following lines:

```bash
<PE SERVICE USER> soft nofile 32768
<PE SERVICE USER> hard nofile 32768
```

---

**Tuning standard installations**

Use these guidelines to configure your installation to maximize its use of available system (CPU and RAM) resources.

PE is composed of multiple services on one or more infrastructure hosts. Each service has multiple settings that can be configured to maximize use of system resources and optimize performance. The default settings for each service are conservative, because the set of services sharing resources on each host varies depending on your infrastructure.

Optimized settings vary depending on the complexity and scale of your infrastructure. For example, you might need to allocate more memory per JRuby depending on the number of environments, or the number of agents and their run intervals.

Configure settings after an install or upgrade, or after making changes to infrastructure hosts, including changing the system resources of existing hosts, or adding new hosts, including compilers.

**Related information**

- [Hardware requirements](#) on page 73
These hardware requirements are based on internal testing at Puppet and are meant only as guidelines to help you determine your hardware needs.

**Methods for configuring Puppet Enterprise** on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

**Tune the maximum number of JRuby instances** on page 154
The `jruby_max_active_instances` setting controls the maximum number of JRuby instances to allow on the Puppet Server.

**Configure command processing threads** on page 164
The `command_processing_threads` setting defines how many command processing threads PuppetDB uses to sort incoming data. Each thread can process a single command at a time. The setting defaults to half the number of cores in your system.

**Increase the Java heap size for PE Java services** on page 170
The Java heap size is the Java Virtual Machine (JVM) memory allocated to Java services in Puppet Enterprise (PE). You can use any configuration method you choose. We will use the console to change the Java heap size for console services, Puppet Server, orchestration services, or PuppetDB in the examples below.

**Tuning the PostgreSQL buffer pool size** on page 160
If you are experiencing performance issues or instability with the console, adjust the buffer memory settings for PostgreSQL.

**Master tuning**
These are the default and recommended tuning settings for your master or disaster recovery replica.

Using the `puppet infrastructure tune` command

The `puppet infrastructure tune` command outputs optimized settings for PE services based on recommended guidelines.

When you run `puppet infrastructure tune`, it queries PuppetDB to identify infrastructure hosts and their processor and memory facts, and outputs settings in YAML format for use in Hiera. The command optimizes based on available system resources, not agent load or environment complexity.

The `puppet infrastructure tune` command is compatible with all PE configurations. The command must be run on your master as root.

You can add these options to the `puppet infrastructure tune` command:

- `--memory_per_jruby <MB>` optimizes the Puppet Server service for environment complexity.
- `--current` outputs currently specified settings for PE services in the console and in Hiera, and identifies duplicate settings found in both places.

**Tip:** Specify settings in the console or Hiera, but not both. Console settings take precedence over Hiera settings

For more information about the tune command, run `puppet infrastructure tune --help`.

Writing configuration files

Puppet supports two formats for configuration files that configure settings: valid JSON and Human-Optimized Config Object Notation (HOCON), a JSON superset.

For more information about HOCON itself, see the [HOCON documentation](#).

Configuration file syntax

Refer to these examples when you're writing configuration files to identify correct JSON or HOCON syntax.

**Brackets**

In HOCON, you can omit the brackets `{ ( ) }` around a root object.

<table>
<thead>
<tr>
<th>JSON example</th>
<th>HOCON example</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{</td>
<td>&quot;authorization&quot;: {</td>
</tr>
<tr>
<td>&quot;authorization&quot;: {</td>
<td>&quot;version&quot;: 1</td>
</tr>
<tr>
<td>&quot;version&quot;: 1</td>
<td>}</td>
</tr>
<tr>
<td>}</td>
<td>}</td>
</tr>
</tbody>
</table>

**Quotes**

In HOCON, double quotes around key and value strings are optional in most cases. However, double quotes are required if the string contains the characters *, ^, +, :, or =.

<table>
<thead>
<tr>
<th>JSON example</th>
<th>HOCON example</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;authorization&quot;: {</td>
<td>authorization: {</td>
</tr>
<tr>
<td>&quot;version&quot;: 1</td>
<td>&quot;version&quot;: 1</td>
</tr>
<tr>
<td>}</td>
<td>}</td>
</tr>

Analytics data collection
Some components automatically collect data about how you use Puppet Enterprise. If you want to opt out of providing this data, you can do so, either during or after installing.

Related information
Methods for configuring Puppet Enterprise on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

What data does Puppet Enterprise collect?
Puppet Enterprise (PE) collects the following data when Puppet Server starts or restarts, and again every 24 hours.
License, version, master, and agent information:
- License UUID
- Number of licensed nodes
- Product name
- PE version
- Master's operating system
- Master's public IP address
- Whether the master is running on Microsoft Azure
- The hypervisor the master is running on, if applicable
- Number of nodes in deployment
- Agent operating systems
- Number of agents running each operating system
- Agent versions
- Number of agents running each version of Puppet agent
- All-in-One (AIO) `puppet-agent` package versions
- Number of agents running on Microsoft Azure or Google Cloud Platform, if applicable
- Number of configured disaster recovery replicas, if applicable

Puppet Enterprise feature use information:
- Number of node groups in use
- Number of nodes used in orchestrator jobs after last orchestrator restart
- Mean nodes per orchestrator job
- Maximum nodes per orchestrator job
- Minimum nodes per orchestrator job
- Total orchestrator jobs created after last orchestrator restart
- Number of non-default user roles in use
- Type of certificate autosigning in use
- Number of nodes in the job that were run over Puppet Communications Protocol
- Number of nodes in the job that were run over SSH
- Number of nodes in the job that were run over WinRM
- Number of nodes patched per task run
- Type of operating system on nodes patched in a task run
- Number of patches applied to each node per task run
- Number of patches completed per task run
- Number of nodes with the `pe_patch` module
- Number of nodes with the `pe_patch` module that require patching
- List of Puppet task jobs
- List of Puppet deploy jobs
- List of Puppet task jobs run by plans
- List of file upload jobs run by plans
- List of script jobs run by plans
- List of command jobs run by plans
- List of wait jobs run by plans
- How nodes were selected for the job
- Whether the job was started by the PE admin account
- Number of nodes in the job
- Length of description applied to the job
- Length of time the job ran
- User agent used to start the job (to distinguish between the console, command line, and API)
- UUID used to correlate multiple jobs run by the same user
- Time the task job was run
• How nodes were selected for the job
• Whether the job was started by the PE admin account
• Number of nodes in the job
• Length of description applied to the job
• Whether the job was asked to override agent-configured no-operation (no-op) mode
• Whether app-management was enabled in the orchestrator for this job
• Time the deploy job was run
• Type of version control system webhook
• Whether the request was to deploy all environments
• Whether code-manager will wait for all deploys to finish or error to return a response
• Whether the deploy is a dry-run
• List of environments requested to deploy
• List of deploy requests
• Total time elapsed for all deploys to finish or error
• List of total wait times for deploys specifying --wait option
• Name of environment deployed
• Time needed for r10k to run
• Time spent committing to file sync
• Time elapsed for all environment hooks to run
• List of individual environment deploys
• Puppet classes applied from publicly available modules, with node counts per class

Backup and Restore information:
• Whether user used --force option when running restore
• Scope of restore
• Time in seconds for various restore functions
• Time to check for disk space to restore
• Time to stop PE related services
• Time to restore PE file system components
• Time to migrate PE configuration for new server
• Time to configure PE on newly restored master
• Time to update PE classification for new server
• Time to deactivate the old master node
• Time to restore the pe-orchestrator database
• Time to restore the pe-rbac database
• Time to restore the pe-classifier database
• Time to restore the pe-activity database
• Time to restore the pe-puppetdb database
• Total time to restore
• List of puppet backup restore jobs
• Whether user used --force option when running puppet-backup create
• Whether user used --dir option when running puppet-backup create
• Whether user used --name option when running puppet-backup create
• Scope of backup
• Time in seconds for various back up functions
• Time needed to estimate backup size, disk space needed, and disk space available
• Time to create file system backup
• Time to back up the pe-orchestrator database
• Time to back up the pe-rbac database
• Time to back up the pe-classifier database
• Time to back up the pe-activity database
• Time to back up the pe-puppetdb database
• Time to compress archive file to backup directory
• Time to back up PE related classification
• Total time to back up
• List of puppet-backup create jobs

Puppet Server performance information:
• Total number of JRuby instances
• Maximum number of active JRuby instances
• Maximum number of requests per JRuby instance
• Average number of instances not in use over the process’s lifetime
• Average wait time to lock the JRuby pool
• Average time the JRuby pool held a lock
• Average time an instance spent handling requests
• Average time spent waiting to reserve an instance from the JRuby pool
• Number of requests that timed out while waiting for a JRuby instance
• Amount of memory the JVM starts with
• Maximum amount of memory the JVM is allowed to request from the operating system

Installer information:
• Installation method (express, text, web, repair)
• Current version, if upgrading
• Target version
• Success or failure, and limited information on the type of failure, if an

If PE is installed using an Amazon Web Services Marketplace Image:
• The marketplace name
• Marketplace image billing mode (bring your own license or pay as you go)

While in use, the console collects the following information:
• Pageviews
• Link and button clicks
• Page load time
• User language
• Screen resolution
• Viewport size
• Anonymized IP address

The console does not collect user inputs such as node or group names, user names, rules, parameters, or variables

The collected data is tied to a unique, anonymized identifier for each master and your site as a whole. No personally identifiable information is collected, and the data we collect is never used or shared outside Puppet, Inc.

How does sharing this data benefit you?

We use the data to identify organizations that could be affected by a security issue, alert them to the issue, and provide them with steps to take or fixes to download. In addition, the data helps us understand how people use the product, which helps us improve the product to meet your needs.

How does Puppet use the collected data?

The data we collect is one of many methods we use for learning about our customers. For example, knowing how many nodes you manage helps us develop more realistic product testing. And learning which operating systems are
the most and the least used helps us decide where to prioritize new functionality. By collecting data, we begin to understand you as a customer.

**Opt out during the installation process**
To opt out of data collection during installation, you can set the DISABLE_ANALYTICS environment variable when you run the installer script.

Setting the DISABLE_ANALYTICS environment variable during installation sets puppetenterprise::send_analytics_data: false in pe.conf, opting you out of data collection.

Follow the instructions for your chosen installation method, adding DISABLE_ANALYTICS=1 when you call the installer script, for example:

```
sudo DISABLE_ANALYTICS=1 ./puppet-enterprise-installer
```

**Opt out after installing**
If you've already installed PE and want to disable data collection, follow these steps.

1. In the console, click Node groups, and then click PE Infrastructure.
2. On the Classes tab, on the puppetenterprise::profile::master class, add send_analytics_data as a parameter and set the Value to false.
3. On the Inventory page, select your master node and click Run Puppet.
4. Select your console node and click Run Puppet.

After Puppet runs to enforce the changes on the master and console nodes, you have opted out of data collection.

**Static catalogs in Puppet Enterprise**
A catalog is a document that describes the desired state for each resource that Puppet manages on a node. A master typically compiles a catalog from manifests of Puppet code. A static catalog is a specific type of Puppet catalog that includes metadata that specifies the desired state of any file resources containing source attributes pointing to puppet:// locations on a node.

The metadata in a static catalog can refer to a specific version of the file (not just the latest version), and can confirm that the agent is applying the appropriate version of the file resource for the catalog. Because the metadata is provided in the catalog, agents make fewer requests to the master.

See the open source Puppet documentation more information about Resources, File types, and Catalog compilation.

**Related information**
Methods for configuring Puppet Enterprise on page 151
After you've installed Puppet Enterprise (PE), optimize it for your environment by configuring and tuning settings as needed. For example, you might want to add your own certificate to the whitelist, increase the max-threads setting for http and https requests, or configure the number of JRuby instances.

**Enabling static catalogs**
When a master produces a non-static catalog, the catalog doesn't specify the version of file resources. When the agent applies the catalog, it always retrieves the latest version of that file resource, or uses a previously retrieved version if it matches the latest version's contents.

This potential problem affects file resources that use the source attribute. File resources that use the content attribute are not affected, and their behavior does not change in static catalogs.

When a manifest depends on a file whose contents change more frequently than the agent receives new catalogs, a node might apply a version of the referenced file that doesn't match the instructions in the catalog. In Puppet Enterprise (PE), such situations are particularly likely if you've configured your agents to run off cached catalogs for participation in application orchestration services.
Consequently, the agent's Puppet runs might produce different results each time the agent applies the same catalog. This often causes problems because Puppet generally expects a catalog to produce the same results each time it's applied, regardless of any code or file content updates on the master.

Additionally, each time an agent applies a normal cached catalog that contains file resources sourced from `puppet://` locations, the agent requests file metadata from the master each time the catalog's applied, even though nothing's changed in the cached catalog. This causes the master to perform unnecessary resource-intensive checksum calculations for each file resource.

Static catalogs avoid these problems by including metadata that refers to a specific version of the resource's file. This prevents a newer version from being incorrectly applied, and avoids having the agent regenerate the metadata on each Puppet run. The metadata is delivered in the form of a unique hash maintained, by default, by the file sync service.

We call this type of catalog "static" because it contains all of the information that an agent needs to determine whether the node's configuration matches the instructions and state of file resources at the static point in time when the catalog was generated.

**Differences in catalog behavior**

Without static catalogs enabled:

- The agent sends facts to the master and requests a catalog.
- The master compiles and returns the agent's catalog.
- The agent applies the catalog by checking each resource the catalog describes. If it finds any resources that are not in the desired state, it makes the necessary changes.

With static catalogs enabled:

- The agent sends facts to the master and requests a catalog.
- The master compiles and returns the agent's catalog, including metadata that that specifies the desired state of the node's file resources.
- The agent applies the catalog by checking each resource the catalog describes. If the agent finds any resources that are not in the desired state, it makes the necessary changes based on the state of the file resources at the static point in time when the catalog was generated.
- If you change code on the master, file contents are not updated until the agent requests a new catalog with new file metadata.

**Enabling file sync**

In PE, static catalogs are disabled across all environments for new installations. To use static catalogs in PE, you must enable file sync. After file sync is enabled, Puppet Server automatically creates static catalogs containing file metadata for eligible resources, and agents running Puppet 1.4.0 or newer can take advantage of the catalogs' new features.

If you do not enable file sync and Code Manager, you can still use static catalogs, but you need to create some custom scripts and set a few parameters in the console.

**Enforcing change with static catalogs**

When you are ready to deploy new Puppet code and deliver new static catalogs, you don’t need to wait for agents to check in. Use the Puppet orchestrator to enforce change and deliver new catalogs across your PE infrastructure, on a per-environment basis.

**When aren’t static catalogs applied?**

In the following scenarios, either agents won't apply static catalogs, or catalogs won't include metadata for file resources.

- Static catalogs are globally disabled.
- Code Manager and file sync are disabled, and `code_id` and `code_content` aren't configured.
- Your agents aren't running PE 2016.1 or later (Puppet agent version 1.4.0 or later).

Additionally, Puppet won't include metadata for a file resource if it:
- Uses the content attribute instead of the source attribute.
- Uses the source attribute with a non-Puppet scheme (for example source => 'http://host:port/path/to/file').
- Uses the source attribute without the built-in modules mount point.
- Uses the source attribute, but the file on the master is not in /etc/puppetlabs/code/environments/<environment>/*/*/files/**. For example, module files are typically in /etc/puppetlabs/code/environments/<environment>/modules/<module_name>/files/**.

Agents continue to process the catalogs in these scenarios, but without the benefits of inlined file metadata or file resource versions.

**Related information**

- Enabling or disabling file sync on page 637
File sync is normally enabled or disabled automatically along with Code Manager.

- Running jobs with Puppet orchestrator on page 429
With the Puppet orchestrator, you can run three types of "jobs": on-demand Puppet jobs, task runs, and plan runs.

**Disabling static catalogs globally with Hiera**

You can turn off all use of static catalogs with a Hiera setting.

To disable static catalogs using Hiera:

1. Add the following code to your default .yaml file and set the parameter to false:

   puppet_enterprise::master::static_catalogs: false

2. To compile changes, run puppet agent -t

**Using static catalogs without file sync**

To use static catalogs without enabling file sync, you must set the code_id and code_content parameters in Puppet, and then configure the code_id_command, code_content_command, and file_sync_enabled parameters in the console.

1. Set code_id and code_content by following the instructions in the open source Puppet static catalogs documentation. Then return to this page to set the remaining parameters.

2. In the console, click Node groups, and in the PE Infrastructure node group, select the PE Master node group.

3. On the Classes tab, locate the puppet_enterprise::profile::master class, and select file_sync_enabled from its Parameter list.

4. In the Value field, enter false, and click Add parameter.

5. Select the code_id_command parameter, and in the Value field, enter the absolute path to the code_id script, and click Add parameter.

6. Select the code_content_command parameter, and in the Value field, add the absolute to the code_content script, and click Add parameter.

7. Commit changes.

8. Run Puppet on the master.

**Related information**

- Running Puppet on nodes on page 294
Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

**Configuring disaster recovery**

Enabling disaster recovery for Puppet Enterprise ensures that your systems can fail over to a replica of your master if infrastructure components become unreachable.

- [Disaster recovery](#) on page 183
  Disaster recovery creates a replica of your master.

- Configure disaster recovery on page 187
  To configure disaster recovery, you must provision a replica to serve as backup during failovers. If your master is permanently disabled, you can then promote a replica.

**Disaster recovery**

Disaster recovery creates a replica of your master.

You can have only one replica at a time, and you can add disaster recovery to an installation with or without compilers. Disaster recovery isn't supported with standalone PE-PostgreSQL or FIPS-compliant installations.

There are two main advantages to enabling disaster recovery:

- If your master fails, the replica takes over, continuing to perform critical operations.
- If your master can't be repaired, you can promote the replica to master. Promotion establishes the replica as the new, permanent master.

**Related information**

What happens during failovers on page 184
Failover occurs when the replica takes over services usually performed by the master.

**Disaster recovery architecture**

The replica is not an exact copy of the master. Rather, the replica duplicates specific infrastructure components and services. Hiera data and other custom configurations are not replicated.

Replication can be **read-write**, meaning that data can be written to the service or component on either the master or the replica, and the data is synced to both nodes. Alternatively, replication can be **read-only**, where data is written only to the master and synced to the replica. Some components and services, like Puppet Server and the console service UI, are not replicated because they contain no native data.

Some components and services are activated immediately when you enable a replica; others aren't active until you promote a replica. After you provision and enable a replica, it serves as a compiler, redirecting PuppetDB and cert requests to the master.

<table>
<thead>
<tr>
<th>Component or service</th>

</tr>
</tbody>
</table>
### Important:
When you enable disaster recovery, you must use Hiera or `pe.conf` only — not the console — to specify configuration parameters. Using `pe.conf` or Hiera ensures that configuration is applied to both your master and replica.

In a standard installation, when a Puppet run fails over, agents communicate with the replica instead of the master. In a large or extra-large installation with compilers, agents communicate with load balancers or compilers, which communicate with the master or replica.

#### Related information

**Configure settings with Hiera** on page 152

Hiera is a hierarchy-based method of configuration management that relies on a “defaults, with overrides” system. When you add a parameter or setting to your Hiera data, Hiera searches through the data in the order it was written to find the value you want to change. Once found, it overrides the default value with the new parameter or setting. You can use Hiera to manage your PE configuration settings.

### What happens during failovers

Failover occurs when the replica takes over services usually performed by the master.

Failover is automatic — you don’t have to take action to activate the replica. With disaster recovery enabled, Puppet runs are directed first to the master. If the master is either fully or partially unreachable, runs are directed to the replica.

In partial failovers, Puppet runs can use the server, node classifier, or PuppetDB on the replica if those services aren’t reachable on the master. For example, if the master’s node classifier fails, but its Puppet Server is still running, agent runs use the Puppet Server on the master but fail over to the replica’s node classifier.

What works during failovers:
- Scheduled Puppet runs
- Catalog compilation
- Viewing classification data using the node classifier API
- Reporting and queries based on PuppetDB data

What doesn’t work during failovers:
- Deploying new Puppet code
- Editing node classifier data
- Using the console
- Certificate functionality, including provisioning new agents, revoking certificates, or running the `puppet certificate` command
- Most CLI tools
- Application orchestration

### System and software requirements for disaster recovery

Your Puppet infrastructure must meet specific requirements in order to configure disaster recovery.

<table>
<thead>
<tr>
<th>Component</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operating system</td>
<td>All supported PE master platforms.</td>
</tr>
<tr>
<td>Component</td>
<td>Requirement</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Software  | • You must use Code Manager so that code is deployed to both the master and the replica after you enable a replica.  
• You must use the default PE node classifier so that disaster recovery classification can be applied to nodes.  
• Orchestrator must be enabled so that agents are updated when you provision or enable a replica. Orchestrator is enabled by default. |
| Replica   | • Must be an agent node that doesn’t have a specific function already. You can decommission a node, uninstall all puppet packages, and re-commission the node to be a replica. However, a compiler cannot perform two functions, for example, as a compiler and a replica.  
• Must have the same hardware specifications and capabilities as your master node. |
| Firewall  | Both the master and the replica must comply with these port requirements:  
• Firewall configuration for installations with compilers. These requirements apply whether your disaster recovery environment uses a single master or compilers.  
• Port 5432 must be open to facilitate database replication by console services. |
| Node names| • You must use resolvable domain names when specifying node names for the master and replica. |
| RBAC tokens| • You must have an admin RBAC token when running puppet infrastructure commands, including provision, enable, and forget. You can generate a token using the puppet-access command.  
**Note:** You don’t need an RBAC token to promote a replica. |

**Related information**

- **Managing and deploying Puppet code** on page 577
  Puppet Enterprise (PE) includes built-in tools for managing and deploying your Puppet infrastructure. Code Manager and r10k are code management tools that automatically install modules, create and maintain environments, and deploy new code to your masters, all based on version control of your Puppet code and data.

- **Configure the orchestrator and pe-orchestration-services** on page 166
  There are several optional parameters you can add to configure the behavior of the orchestrator and pe-orchestration-services. Because they are profile classes, you can change these in the console in the PE Orchestrator group.

- **Firewall configuration for large installations with compilers** on page 86
  These are the port requirements for large installations with compilers.

- **Generate a token using puppet-access** on page 209

© 2020 Puppet, Inc.
Use `puppet-access` to generate an authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master.

### Classification changes in disaster recovery installations

When you provision and enable a replica, the system makes a number of classification changes in order to manage disaster recovery without affecting existing configuration.

These preconfigured node groups are added in disaster recovery installations:

<table>
<thead>
<tr>
<th>Node group</th>
<th>Matching nodes</th>
<th>Inherits from</th>
</tr>
</thead>
<tbody>
<tr>
<td>PE HA Master</td>
<td>master</td>
<td>PE Master node group</td>
</tr>
<tr>
<td>PE HA Replica</td>
<td>master replicas</td>
<td>PE Infrastructure node group</td>
</tr>
</tbody>
</table>

These parameters are used to configure disaster recovery installations:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Purpose</th>
<th>Node group</th>
<th>Classes</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>agent-server-urls</code></td>
<td>Specifies the list of servers that agents contact, in order.</td>

© 2020 Puppet, Inc.
Load balancer timeout in disaster recovery installations

Disaster recovery configuration uses timeouts to determine when to fail over to the replica. If the load balancer timeout is shorter than the server and agent timeout, connections from agents might be terminated during failover.

To avoid timeouts, set the timeout option for load balancers to four minutes or longer. This duration allows compilers enough time for required queries to PuppetDB and the node classifier service. You can set the load balancer timeout option using parameters in the haproxy or f5 modules.

Configure disaster recovery

To configure disaster recovery, you must provision a replica to serve as backup during failovers. If your master is permanently disabled, you can then promote a replica.

Before you begin

Apply disaster recovery system and software requirements.

Tip: The puppet infrastructure commands, which are used to configure and manage disaster recovery, require a valid admin RBAC token and must be run from a root session. Running with elevated privileges via sudo puppet infrastructure is not sufficient. Instead, start a root session by running sudo su -, and then run the puppet infrastructure command. For details about these commands, run puppet infrastructure help <ACTION>, for example, puppet infrastructure help provision.

Related information

Generate a token using puppet-access on page 209
Use puppet-access to generate an authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master.

Provision and enable a replica

Provisioning a replica duplicates specific components and services from the master to the replica. Enabling a replica activates most of its duplicated services and components, and instructs agents and infrastructure nodes how to communicate in a failover scenario.

Before you begin

• Ensure you have a valid admin RBAC token.
• Move any tuning parameters that you set for your master using the console to Hiera. Using Hiera ensures configuration is applied to both your master and replica.
• Back up your classifier hierarchy, because enabling a replica alters classification.

Note: While completing this task, the master is unavailable to serve catalog requests. Time completing this task accordingly.
1. Configure infrastructure agents to connect orchestration agents to the master.
   a) In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Infrastructure Agent** group.
   b) If you manage your load balancers with agents, on the **Rules** tab, pin load balancers to the group.
   c) On the **Classes** tab, find the **puppet_enterprise::profile::agent** class and specify these parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>manage_puppet_conf</td>
<td>Specify <code>true</code> to ensure that your setting for <code>server_list</code> is configured in the expected location and persists through Puppet runs.</td>
</tr>
<tr>
<td>pcp_broker_list</td>
<td>Hostname for your master. Hostnames must include port 8142, for example <code>&quot;MASTER.EXAMPLE.COM:8142&quot;</code>.</td>
</tr>
<tr>
<td>master_uris</td>
<td>Hostname for your master, for example <code>&quot;MASTER.EXAMPLE.COM&quot;</code>. This setting assumes port 8140 unless you specify otherwise with <code>host:port</code>.</td>
</tr>
<tr>
<td>server_list</td>
<td>Hostname for your master, for example <code>&quot;MASTER.EXAMPLE.COM&quot;</code>. This setting assumes port 8140 unless you specify otherwise with <code>host:port</code>.</td>
</tr>
</tbody>
</table>

   d) Remove any values set for `pcp_broker_ws_uris`.
   e) Commit changes.
   f) Run Puppet on all agents classified into the **PE Infrastructure Agent** group.

2. Pin the node that you want to provision to the **PE Infrastructure Agent** group and run Puppet on the node:
   ```
puppet agent -t
   ```

3. On the master, as the root user, run `puppet infrastructure provision replica <REPLICA NODE NAME> --enable`

   **Note:** In installations with compile masters, use the `--skip-agent-config` flag with the `--enable` option if you want to:
   - Upgrade a replica without needing to run Puppet on all agents.
   - Add disaster recovery to an installation without modifying the configuration of existing load balancers.
   - Manually configure which load balancer agents communicate with in geo-diverse installations. See **Managing agent communication in geo-diverse installations** on page 189.

4. Copy your secret key file from the master to the replica. The path to the secret key file is `/etc/puppetlabs/orchestration-services/conf.d/secrets/keys.json`.

   **Important:** If you do not copy your secret key file onto your replica, the replica generates a new secret key when you promote it. The new key prevents you from accessing credentials for your agentless nodes or running tasks and plans on agentless nodes.

5. Optional: Verify that all services running on the master are also running on the replica:
   a) From the master, run `puppet infrastructure status --verbose` to verify that the replica is available.
   b) From any managed node, run `puppet agent -t --noop --server_list=<REPLICA HOSTNAME>`. If the replica is correctly configured, the Puppet run succeeds and shows no changed resources.

6. Optional: Deploy updated configuration to agents by running Puppet, or wait for the next scheduled Puppet run.

   If you used the `--skip-agent-config` option, you can skip this step.

   **Note:** If you use the direct Puppet workflow, where agents use cached catalogs, you must manually deploy the new configuration by running `puppet job run --no-enforce-environment --query 'nodes {deactivated is null and expired is null}'`
7. Optional: Perform any tests you feel are necessary to verify that Puppet runs continue to work during failover. For example, to simulate an outage on the master:
   a) Prevent the replica and a test node from contacting the master. For example, you might temporarily shut down the master or use `iptables` with drop mode.
   b) Run `puppet agent -t` on the test node. If the replica is correctly configured, the Puppet run succeeds and shows no changed resources. Runs might take longer than normal when in failover mode.
   c) Reconnect the replica and test node.

**Related information**

- **Generate a token using puppet-access** on page 209
  Use `puppet-access` to generate an authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master.

- **Configure settings with Hiera** on page 152
  Hiera is a hierarchy-based method of configuration management that relies on a “defaults, with overrides” system. When you add a parameter or setting to your Hiera data, Hiera searches through the data in the order it was written to find the value you want to change. Once found, it overrides the default value with the new parameter or setting. You can use Hiera to manage your PE configuration settings.

- **Back up your infrastructure** on page 647
  PE backup creates a copy of your Puppet master, including configuration, certificates, code, and PuppetDB.

- **Running Puppet on nodes** on page 294
  Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

- **Direct Puppet: a workflow for controlling change** on page 438
  The orchestrator—used alongside other PE tools, such as Code Manager—allows you to control when and how infrastructure changes are made before they reach your production environment.

**Managing agent communication in geo-diverse installations**

Typically, when you enable a replica using `puppet infrastructure enable replica`, the configuration tool automatically sets the same communication parameters for all agents. In *geo-diverse installations*, with load balancers or compilers in multiple locations, you must manually configure agent communication settings so that agents fail over to the appropriate load balancer or compiler.

To skip automatically configuring which Puppet servers and PCP brokers agents communicate with, use the `--skip-agent-config` flag when you provision and enable a replica, for example:

```
puppet infrastructure provision replica example.puppet.com --enable --skip-agent-config
```

To manually configure which load balancer or compiler agents communicate with, use one of these options:

- **CSR attributes**
  1. For each node, include a CSR attribute that identifies the location of the node, for example `pp_region` or `pp_datacenter`.
  2. Create child groups off of the **PE Agent** node group for each location.
  3. In each child node group, include the `puppet_enterprise::profile::agent` module and set the `server_list` parameter to the appropriate load balancer or compiler hostname.
  4. In each child node group, add a rule that uses the trusted fact created from the CSR attribute.

- **Hiera**
  For each node or group of nodes, create a key/value pair that sets the `puppet_enterprise::profile::agent::server_list` parameter to be used by the **PE Agent** node group.

- **Custom method** that sets the `server_list` parameter in `puppet.conf`
**Promote a replica**

If your master can’t be restored, you can promote the replica to master to establish the replica as the new, permanent master.

1. Verify that the master is permanently offline.
   
   If the master comes back online during promotion, your agents can get confused trying to connect to two active masters.

2. On the replica, as the root user, run `puppet infrastructure promote replica`
   
   Promotion can take up to the amount of time it took to install PE initially. Don’t make code or classification changes during or after promotion.

3. When promotion is complete, update any systems or settings that refer to the old master, such as PE client tool configurations, Code Manager hooks, and CNAME records.

4. Deploy updated configuration to nodes by running Puppet or waiting for the next scheduled run.
   
   **Note:** If you use the direct Puppet workflow, where agents use cached catalogs, you must manually deploy the new configuration by running `puppet job run --no-enforce-environment --query 'nodes {deactivated is null and expired is null}'`

5. Optional: Provision a new replica in order to maintain disaster recovery.
   
   **Note:** Agent configuration must be updated before provisioning a new replica. If you re-use your old master’s node name for the new replica, agents with outdated configuration might use the new replica as a master before it’s fully provisioned.

**Related information**

*Running Puppet on nodes* on page 294

Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

*Direct Puppet: a workflow for controlling change* on page 438

The orchestrator—used alongside other PE tools, such as Code Manager—allows you to control when and how infrastructure changes are made before they reach your production environment.

**Enable a new replica using a failed master**

After promoting a replica, you can use your old master as a new replica, effectively swapping the roles of your failed master and promoted replica.

**Before you begin**

The `puppet infrastructure run` command leverages built-in Bolt plans to automate certain management tasks. To use this command, you must be able to connect using SSH from your master to any nodes that the command modifies. You can establish an SSH connection using key forwarding, a local key file, or by specifying keys in `.ssh/config` on your master. For more information, see Bolt OpenSSH configuration options.

To view all available parameters, use the `--help` flag. The logs for all `puppet infrastructure run` Bolt plans are located at `/var/log/puppetlabs/installer/bolt_info.log`.

You must be able to reach the failed master via SSH from the current master.

On your promoted replica, as the root user, run `puppet infrastructure run enable_ha_failover`, specifying these parameters:

- **host** — Hostname of the failed master. This node becomes your new replica.
- **topology** — Architecture used in your environment, either `mono` (standard) or `mono-with-compile` (large).
- **replication_timeout_secs** — Optional. The number of seconds allowed to complete provisioning and enabling of the new replica before the command fails.
- **tmpdir** — Optional. Path to a directory to use for uploading and executing temporary files.
For example:

```bash
puppet infrastructure run enable_ha_failover host=<FAILED_MASTER_HOSTNAME>
topology=mono
```

The failed master is repurposed as a new replica.

### Forget a replica

Forgetting a replica cleans up classification and database state, preventing degraded performance over time.

**Before you begin**

Ensure you have a valid admin RBAC token.

Run the `forget` command whenever a replica node is destroyed, even if you plan to replace it with a replica with the same name.

1. Verify that the replica to be removed is permanently offline.
2. On the master, as the root user, run `puppet infrastructure forget <REPLICA NODE NAME>`
3. Delete your secret key file from the replica because leaving sensitive information on a replica poses a security risk. The path to the secret key file is `/etc/puppetlabs/orchestration-services/conf.d/secrets/keys.json`

The replica is decommissioned, the node is purged as an agent, secret key information is deleted, and a Puppet run is completed on the master.

**Related information**

- [Generate a token using puppet-access on page 209](#)
- **Use puppet-access** to generate an authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master.

### Reinitialize a replica

If you encounter certain errors on your replica after provisioning, you can reinitialize the replica. Reinitializing destroys and re-creates replica databases, as specified.

**Before you begin**

Your master must be fully functional and the replica must be able to communicate with the master.

**CAUTION:** If you reinitialize a functional replica that you already enabled, the replica is unavailable to serve as backup in a failover during reinitialization.

Reinitialization is not intended to fix slow queries or intermittent failures. Reinitialize your replica only if it’s inoperational or you see replication errors.

1. On the replica, as the root user, reinitialize databases as needed:
   - All databases: `puppet infrastructure reinitialize replica`
   - Specific databases: `puppet infrastructure reinitialize replica --db <DATABASE>` where `<DATABASE>` is `pe-activity`, `pe-classifier`, `pe-orchestrator`, or `pe-rbac`.
2. Follow prompts to complete the reinitialization.

### Accessing the console

The console is the web interface for Puppet Enterprise.

Use the console to:

- Manage node requests to join the Puppet deployment.
• Assign Puppet classes to nodes and groups.
• Run Puppet on specific groups of nodes.
• View reports and activity graphs.
• Browse and compare resources on your nodes.
• View package and inventory data.
• Manage console users and their access privileges.

Reaching the console

The console is served as a website over SSL, on whichever port you chose when installing the console component.

Let's say your console server is console.domain.com. If you chose to use the default port (443), you can omit the port from the URL and reach the console by navigating to https://console.domain.com.

If you chose to use port 8443, you reach the console at https://console.domain.com:8443.

Remember: Always use the https protocol handler. You cannot reach the console over plain http.

Accepting the console's certificate

The console uses an SSL certificate created by your own local Puppet certificate authority. Because this authority is specific to your site, web browsers won't know it or trust it, and you must add a security exception in order to access the console.

Adding a security exception for the console is safe to do. Your web browser warns you that the console's identity hasn't been verified by one of the external authorities it knows of, but that doesn't mean it's untrustworthy. Because you or another administrator at your site is in full control of which certificates the Puppet certificate authority signs, the authority verifying the site is you.

When your browser warns you that the certificate authority is invalid or unknown:

• In Chrome, click Advanced, then Proceed to <CONSOLE ADDRESS>.
• In Firefox, click Advanced, then Add exception.
• In Internet Explorer or Microsoft Edge, click Continue to this website (not recommended).
• In Safari, click Continue.

Logging in

Accessing the console requires a username and password.

If you are an administrator setting up the console or accessing it for the first time, use the username and password you chose when you installed the console. Otherwise, get credentials from your site's administrator.

Because the console is the main point of control for your infrastructure, it is a good idea to prohibit your browser from storing the login credentials.

Generate a user password reset token

When users forget passwords or lock themselves out of the console by attempting to log in with incorrect credentials too many times, you need to generate a password reset token.

1. In the console, on the Access control page, click the Users tab.
2. Click the name of the user who needs a password reset token.
3. Click Generate password reset. Copy the link provided in the message and send it to the user.
Reset the console administrator password

To reset the administrator password for console access, use the `puppet infrastructure` command.

Log into the node running console services and reset the console admin password: `puppet infrastructure console_password --password=<MY_PASSWORD>

Troubleshooting login to the PE admin account

If your directory contains multiple users with a login name of "admin," the PE admin account is unable to log in.

If you are locked out of PE as the admin user and there are no other users with administrator access who you can ask to reset the access control settings in the console, SSH into the box and use curl commands to reset the directory service settings.

For a box named centos7 the curl call looks like this:

Bash

```bash

type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/rbac-api/v1/ds"
data='{}'

curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key"
--request PUT "$uri" --data "$data"
```

Managing access

Role-based access control, more succinctly called RBAC, is used to grant individual users the permission to perform specific actions. Permissions are grouped into user roles, and each user is assigned at least one user role.

By using permissions, you give the appropriate level of access and agency to each user. For example, you can grant users:

- The permission to grant password reset tokens to other users who have forgotten their passwords
- The permission to edit a local user’s metadata
- The permission to deploy Puppet code to specific environments
- The permission to edit class parameters in a node group

You can do access control tasks in the console or using the RBAC API.

- **User permissions and user roles** on page 194
  The "role" in role-based access control refers to a system of user roles, which are assigned to user groups and their users. Those roles contain permissions, which define what a user can or can't do within PE.

- **Creating and managing local users and user roles** on page 199
  Puppet Enterprise's role-based access control (RBAC) enables you to manage users—what they can create, edit, or view, and what they can't—in an organized, high-level way that is vastly more efficient than managing user permissions on a per-user basis. User roles are sets of permissions you can apply to multiple users. You can't assign permissions to single users in PE, only to user roles.

- **Connecting external directory services to PE** on page 201
  Puppet Enterprise connects to external Lightweight Directory Access Protocol (LDAP) directory services through its role-based access control (RBAC) service. Because PE integrates with cloud LDAP service providers such as Okta, you can use existing users and user groups that have been set up in your external directory service.
• Working with user groups from an external directory service on page 206
  You don’t explicitly add remote users to PE. Instead, after the external directory service has been successfully
c connected, remote users must log into PE, which creates their user record.
• Token-based authentication on page 208
  Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to
access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions
granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.
• RBAC API v1 on page 213
  The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.
• RBAC API v2 on page 238
  The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.
• Activity service API on page 242
  The activity service logs changes to role-based access control (RBAC) entities, such as users, directory groups, and
user roles.

User permissions and user roles
The "role" in role-based access control refers to a system of user roles, which are assigned to user groups and their
users. Those roles contain permissions, which define what a user can or can't do within PE.

When you add new users to PE, they can't actually do anything until they're associated with a user role, either
explicitly through role assignment or implicitly through group membership and role inheritance. When a user is added
to a role, they receive all the permissions of that role.

There are four default user roles: Administrators, Code Deployers, Operators, and Viewers. In addition, you can
create custom roles.

For example, you might want to create a user role that grants users permission to view but not edit a specific subset of
node groups. Or you might want to divide up administrative privileges so that one user role is able to reset passwords
while another can edit roles and create users.

Permissions are additive. If a user is associated with multiple roles, that user is able to perform all of the actions
described by all of the permissions on all of the applied roles.

Structure of user permissions
User permissions are structured as a triple of type, permission, and object.

• Types are everything that can be acted on, such as node groups, users, or user roles.
• Permissions are what you can do with each type, such as create, edit, or view.
• Objects are specific instances of the type.

Some permissions added to the Administrators user role might look like this:

<table>
<thead>
<tr>
<th>Type</th>
<th>Permission</th>
<th>Object</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node groups</td>
<td>View</td>
<td>PE Master</td>
<td>Gives permission to view the PE Master node group.</td>
</tr>
<tr>
<td>User roles</td>
<td>Edit</td>
<td>All</td>
<td>Gives permission to edit all user roles.</td>
</tr>
</tbody>
</table>

When no object is specified, a permission applies to all objects of that type. In those cases, the object is “All”. This is
denoted by "*" in the API.

In both the console and the API, "*" is used to express a permission for which an object doesn’t make sense, such as
when creating users.

© 2020 Puppet, Inc.
### User permissions

The table below lists the available object types and their permissions, as well as an explanation of the permission and how to use it.

Note that types and permissions have both a display name, which is the name you see in the console interface, and a system name, which is the name you use to construct permissions in the API. In the following table, the display names are used.

<table>
<thead>
<tr>
<th>Type</th>
<th>Permission</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate request</td>
<td>Accept and reject</td>
<td>Accept and reject certificate signing requests. Object must always be &quot;*&quot;.</td>
</tr>
<tr>
<td>Console</td>
<td>View</td>
<td>View the PE console. Object must always be &quot;*&quot;.</td>
</tr>
<tr>
<td>Directory service</td>
<td>View, edit, and test</td>
<td>View, edit, and test directory service settings. Object must always be &quot;*&quot;.</td>
</tr>
<tr>
<td>Job orchestrator</td>
<td>Start, stop and view jobs</td>
<td>Start and stop jobs and tasks, view jobs and job progress, and view an inventory of nodes that are connected to the PCP broker.</td>
</tr>
<tr>
<td>Node groups</td>
<td>Create, edit, and delete child groups</td>
<td>Create new child groups, delete existing child groups, and modify every attribute of child groups except environment. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Node groups</td>
<td>Edit child group rules</td>
<td>Edit the rules of descendents of a node group. This does not grant the ability to edit the rules of the group in the object field, only children of that group. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Node groups</td>
<td>Edit classes, parameters, and variables</td>
<td>Edit every attribute of a node group except its environment and rule. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Node groups</td>
<td>Edit configuration data</td>
<td>Edit parameterized configuration data on a node group. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Node groups</td>
<td>Edit parameters and variables</td>
<td>Edit the class parameters and variables of a node group's classes. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Node groups</td>
<td>Set environment</td>
<td>Set the environment of a node group. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Type</td>
<td>Permission</td>
<td>Definition</td>
</tr>
<tr>

<td>-----------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Node groups</td>
<td>View</td>
<td>See all attributes of a node group, most notably the values of class parameters and variables. This permission is inherited by all descendents of the node group.</td>
</tr>
<tr>
<td>Nodes</td>
<td>Edit node data from PuppetDB</td>
<td>Edit node data imported from PuppetDB. Object must always be &quot;* *&quot;.</td>
</tr>
<tr>
<td>Nodes</td>
<td>View node data from PuppetDB</td>
<td>View node data imported from PuppetDB. Object must always be &quot;* *&quot;.</td>
</tr>
<tr>
<td>Nodes</td>
<td>View sensitive connection information in inventory service</td>
<td>View sensitive parameters stored in the inventory service for a connection. For example, user credentials. Object must always be &quot;* *&quot;.</td>
</tr>
<tr>
<td>Plans</td>
<td>Run plans</td>
<td>Run specific plans on all nodes.</td>
</tr>
<tr>
<td>Puppet agent</td>
<td>Run Puppet on agent nodes</td>
<td>Trigger a Puppet run from the console or orchestrator. Object must always be &quot;* *&quot;.</td>
</tr>
<tr>
<td>Puppet environment</td>
<td>Deploy code</td>
<td>Deploy code to a specific PE environment.</td>
</tr>
<tr>
<td>Puppet Server</td>
<td>Compile catalogs for remote nodes</td>
<td>Compile a catalog for any node managed by this PE instance. This permission is required to run impact analysis tasks in Continuous Delivery for Puppet Enterprise.</td>
</tr>
<tr>
<td>Tasks</td>
<td>Run tasks</td>
<td>Run specific tasks on all nodes, a selected node group, or nodes that match a PQL query.</td>
</tr>
<tr>
<td>User groups</td>
<td>Delete</td>
<td>Delete a user group. This can be granted per group.</td>
</tr>
<tr>
<td>User groups</td>
<td>Import</td>
<td>Import groups from the directory service for use in RBAC. Object must always be &quot;* *&quot;.</td>
</tr>
<tr>
<td>User roles</td>

**Related information**

Permissions endpoints on page 226

You assign permissions to user roles to manage user access to objects. The permissions endpoints enable you to get information about available objects and the permissions that can be constructed for those objects.

**Working with node group permissions**

Node groups in the node classifier are structured hierarchically; therefore, node group permissions inherit. Users with specific permissions on a node group implicitly receive the permissions on any child groups below that node group in the hierarchy.

Two types of permissions affect a node group: those that affect a group itself, and those that affect the group's child groups. For example, giving a user the "Set environment" permission on a group allows the user to set the environment for that group and all of its children. On the other hand, assigning "Edit child group rules" to a group allows a user to edit the rules for any child group of a specified node group, but not for the node group itself. This allows some users to edit aspects of a group, while other users can be given permissions for all children of that group without being able to affect the group itself.

Due to the hierarchical nature of node groups, if a user is given a permission on the default (All) node group, this is functionally equivalent to giving them that permission on "* *".
Best practices for assigning permissions

Working with user permissions can be a little tricky. You don't want to grant users permissions that essentially escalate their role, for example. The following sections describe some strategies and requirements for setting permissions.

Grant edit permissions to users with create permissions

Creating new objects doesn't automatically grant the creator permission to view those objects. Therefore, users who have permission to create roles, for example, must also be given permission to edit roles, or they won't be able to see new roles that they create. Our recommendation is to assign users permission to edit all objects of the type that they have permission to create. For example:

<table>
<thead>
<tr>
<th>Type</th>
<th>Permission</th>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>User roles</td>
<td>Edit members</td>
<td>All (or &quot;*&quot;)</td>
</tr>
<tr>
<td>Users</td>
<td>Edit</td>
<td>All (or &quot;*&quot;)</td>
</tr>
</tbody>
</table>

Avoid granting overly permissive permissions

Operators, a default role in PE, have many of the same permissions as Administrators. However, we've intentionally limited this role's ability to edit user roles. This way, members of this group can do many of the same things as Administrators, but they can't edit (or enhance) their own permissions.

Similarly, avoid granting users more permissions than their roles allow. For example, if users have the roles:edit:* permission, they are able to add the node_groups:view:* permission to the roles they belong to, and subsequently see all node groups.

Give permission to edit directory service settings to the appropriate users

The directory service password is not redacted when the settings are requested in the API. Give directory_service:edit:* permission only to users who are allowed see the password and other settings.

The ability to reset passwords should be given only with other password permissions

The ability to help reset passwords for users who forgot them is granted by the users:reset_password:<instance> permission. This permission has the side effect of reinstating revoked users after the reset token is used. As such, the reset password permission should be given only to users who are also allowed to revoke and reinstate other users.

Creating and managing local users and user roles

Puppet Enterprise’s role-based access control (RBAC) enables you to manage users—what they can create, edit, or view, and what they can't—in an organized, high-level way that is vastly more efficient than managing user permissions on a per-user basis. User roles are sets of permissions you can apply to multiple users. You can't assign permissions to single users in PE, only to user roles.

Remember: Each user must be assigned to one or more roles before they can log in and use PE.

Note: Puppet stores local accounts and directory service integration credentials securely. Local account passwords are hashed using SHA-256 multiple times along with a 32-bit salt. Directory service lookup credentials configured for directory lookup purposes are encrypted using AES-128. Puppet does not store the directory credentials used for authenticating to Puppet. These are different from the directory service lookup credentials.

Create a new user

These steps add a local user.

To add users from an external directory, see Working with user groups from an external directory.
1. In the console, on the Access control page, click the Users tab.
2. In the Full name field, enter the user's full name.
3. In the Login field, enter a username for the user.
4. Click Add local user.

Give a new user access to the console
When you create new local users, you need to send them a password reset token so that they can log in for the first time.
1. On the Access control page, on the Users tab, select the user's full name.
2. Click Generate password reset.
3. Copy the link provided in the message and send it to the new user.

Create a new user role
RBAC has four predefined roles: Administrators, Code Deployers, Operators, and Viewers. You can also define your own custom user roles.

Users with the appropriate permissions, such as Administrators, can define custom roles. To avoid potential privilege escalation, only users who are allowed all permissions should be given the permission to edit user roles.
1. In the console, on the Access control page, click the User roles tab.
2. In the Name field, enter a name for the new user role.
3. (Optional) In the Description field, enter a description of the new user role.
4. Click Add role.

Assign permissions to a user role
You can mix and match permissions to create custom user roles that provide users with precise levels of access to PE actions.

Before you begin
Review User permissions and user roles, which includes important information about how permissions work in PE.

Assign permissions to a user role
You can mix and match permissions to create custom user roles that provide users with precise levels of access to PE actions.

Before you begin
Review User permissions and user roles, which includes important information about how permissions work in PE.

1. On the Access control page, on the User roles tab, select a user role.
2. Click Permissions.
3. In the Type field, select the type of object you want to assign permissions for, such as Node groups.
4. In the Permission field, select the permission you want to assign, such as View.
5. In the Object field, select the specific object you want to assign the permission to. For example, if you are setting a permission to view node groups, select a specific node group this user role has permissions to view.
6. Click Add permission, and commit changes.

Related information
Best practices for assigning permissions on page 199
Working with user permissions can be a little tricky. You don't want to grant users permissions that essentially escalate their role, for example. The following sections describe some strategies and requirements for setting permissions.

Add a user to a user role
When you add users to a role, the user gains the permissions that are applied to that role. A user can't do anything in PE until they have been assigned to a role.

1. On the Access control page, on the User roles tab, select a user role.
2. Click Member users.
3. In the User name field, select the user you want to add to the user role.
4. Click Add user, and commit changes.

**Remove a user from a user role**
You can change a user's permissions by removing them from a user role. The user loses the permissions associated with the role, and won't be able to do anything in PE until they are assigned to a new role.

1. On the Access control page, on the User roles tab, select a user role.
2. Click Member users.
3. Locate the user you want to remove from the user role. Click Remove, and commit changes.

**Revoke a user's access**
If you want to remove a user's access to PE but not delete their account, you can revoke them. Revocation is also what happens when a user is locked out from too many incorrect password attempts.

1. In the console, on the Access control page, click the Users tab.
2. In the Full name column, select the user you want to revoke.
3. Click Revoke user access.

**Delete a user**
You can delete a user through the console. Note, however, that this action deletes only the user's Puppet Enterprise account, not the user's listing in any external directory service.

Deletion removes all data about the user except for their activity data, which continues to be stored in the database and remains viewable through the API.

1. In the console, on the Access control page, click the Users tab.
2. In the Full name column, locate the user you want to delete.
3. Click Remove.

**Delete a user role**
You can delete a user role through the console.

When you delete a user role, users lose the permissions that the role gives them. This can impact their access to Puppet Enterprise if they have not been assigned other user roles.

1. In the console, on the Access control page, click the User roles tab.
2. In the Name column, locate the role you want to delete.
3. Click Remove.

**Connecting external directory services to PE**
Puppet Enterprise connects to external Lightweight Directory Access Protocol (LDAP) directory services through its role-based access control (RBAC) service. Because PE integrates with cloud LDAP service providers such as Okta, you can use existing users and user groups that have been set up in your external directory service.

Specifically, you can:

- Authenticate external directory users.
• Authorize access of external directory users based on RBAC permissions.
• Store and retrieve the groups and group membership information that has been set up in your external directory.

**Note:** Puppet stores local accounts and directory service integration credentials securely. Local account passwords are hashed using SHA-256 multiple times along with a 32-bit salt. Directory service lookup credentials configured for directory lookup purposes are encrypted using AES-128. Puppet does not store the directory credentials used for authenticating to Puppet. These are different from the directory service lookup credentials.

PE supports OpenLDAP and Active Directory. If you have predefined groups in your Active Directory or OpenLDAP directory, you can import these groups into the console and assign user roles to them. Users in an imported group inherit the permissions specified in assigned user roles. If new users are added to the group in the external directory, they also inherit the permissions of the role to which that group belongs.

**Note:** The connection to your external LDAP directory is read-only. If you want to make changes to remote users or user groups, you need to edit the information directly in the external directory.

**Connect to an external directory service**

PE connects to the external directory service when a user logs in or when groups are imported. The supported directory services are OpenLDAP and Active Directory.

1. In the console, on the Access control page, click the External directory tab.
2. Fill in the directory information.
   
   All fields are required, except for Login help, Lookup user, Lookup password, User relative distinguished name, and Group relative distinguished name.

   If you do not enter User relative distinguished name or Group relative distinguished name, RBAC searches the entire base DN for the user or group.

3. Click Test connection to ensure that the connection has been established. Save your settings after you have successfully tested them.

**Note:** This only tests the connection to the LDAP server. It does not test or validate LDAP queries.

**External directory settings**

The table below provides examples of the settings used to connect to an Active Directory service and an OpenLDAP service to PE. Each setting is explained in more detail below the table.

**Important:** The settings shown in the table are examples. You need to substitute these example settings with the settings used in your directory service.

Explanation of external directory settings

**Directory name** The name that you provide here is used to refer to the external directory service anywhere it is used in the PE console. For example, when you view a remote user in the console, the name that you provide in this field is listed in the console as the source for that user. Set any name of your choice.

**Login help (optional)** If you supply a URL here, a "Need help logging in?" link is displayed on the login screen. The href attribute of this link is set to the URL that you provide.

**Hostname** The FQDN of the directory service to which you are connecting.

**Port** The port that PE uses to access the directory service. The port is generally 389, unless you choose to connect using SSL, in which case it is generally 636.

**Lookup user (optional)** The distinguished name (DN) of the directory service user account that PE uses to query information about users and groups in the directory server. If a username is supplied, this user must have read access for all directory entries that are to be used in the console. We recommend that this user is restricted to read-only access to the directory service.

If your LDAP server is configured to allow anonymous binding, you do not need to provide a lookup user. In this case, the RBAC service binds anonymously to your LDAP server.

**Lookup password (optional)** The lookup user's password.

If your LDAP server is configured to allow anonymous binding, you do not need to provide a lookup password. In this case, the RBAC service binds anonymously to your LDAP server.

**Connection timeout (seconds)** The number of seconds that PE attempts to connect to the directory server before timing out. Ten seconds is fine in the majority of cases. If you are experiencing timeout errors, make sure the directory service is up and reachable, and then increase the timeout if necessary.

**Connect using:** Select the security protocol you want to use to connect to the external directory: **SSL** and **StartTLS** encrypt the data transmitted. **Plain text** is not a secure connection. In addition, to ensure that the directory service is properly identified, configure the `ds-trust-chain` to point to a copy of the public key for the directory service. For more information, see [Verify directory server certificates](#) on page 206.

**Validate the hostname?** Select **Yes** to verify that the Directory Services hostname used to connect to the LDAP server matches the hostname on the SSL certificate. This option is not available when you choose to connect to the external directory using plain text.
Allow wildcards in SSL certificate? Select Yes to allow a connection to a Directory Services server with a SSL certificates that use a wildcard (*) specification. This option is not available when you choose to connect to the external directory using plain text.

Base distinguished name When PE constructs queries to your external directory (for example to look up user groups or users), the queries consist of the relative distinguished name (RDN) (optional) + the base distinguished name (DN), and are then filtered by lookup/login attributes. For example, if PE wants to authenticate a user named Bob who has the RDN ou=bob,ou=users, it sends a query in which the RDN is concatenated with the DN specified in this field (for example, dc=puppetlabs,dc=com). This gives a search base of ou=bob,ou=users,dc=puppetlabs,dc=com.

The base DN that you provide in this field specifies where in the directory service tree to search for groups and users. It is the part of the DN that all users and groups that you want to use have in common. It is commonly the root DN (example dc=example,dc=com) but in the following example of a directory service entry, you could set the base DN to ou=Puppet,dc=example,dc=com because both the group and the user are also under the organizational unit ou=Puppet.

Example directory service entry

```
# A user named Harold
dn: cn=harold,ou=Users,ou=Puppet,dc=example,dc=com
objectClass: organizationalPerson
cn: harold
displayName: Harold J.
mail: harold@example.com
memberOf: inspectors
sAMAccountName: harold11

# A group Harold is in
dn: cn=inspectors,ou=Groups,ou=Puppet,dc=example,dc=com
objectClass: group
cn: inspectors
displayName: The Inspectors
member: harold
```

User login attribute This is the directory attribute that the user uses to log in to PE. For example, if you specify sAMAccountName as the user login attribute, Harold logs in with the username "harold11" because sAMAccountName=harold11 in the example directory service entry provided above.

The value provided by the user login attribute must be unique among all entries under the User RDN + Base DN search base you’ve set up. For example, say you’ve selected the following settings:

```
base DN = dc=example,dc=com
user RDN = null
user login attribute = cn
```

When Harold tries to log in, the console searches the external directory for any entries under dc=example,dc=com that have the attribute/value pair cn=harold. (This attribute/value pair does not need to be contained within the DN). However, if there is another user named Harold who has the DN cn=harold,ou=OtherUsers,dc=example,dc=com, two results are returned and the login does not succeed because the console does not know which entry to use. Resolve this issue by either narrowing your search base such that only one of the entries can be found, or using a value for login attribute that you know to be unique. This makes sAMAccountName a good choice if you’re using Active Directory, as it must be unique across the entire directory.

User email address The directory attribute to use when displaying the user's email address in PE.

User full name The directory attribute to use when displaying the user's full name in PE.

User relative distinguished name (optional) The user RDN that you set here is concatenated with the base DN to form the search base when looking up a user. For example, if you specify ou=users for the
user RDN, and your base DN setting is ou=Puppet, dc=example, dc=com, PE finds users that have ou=users, ou=Puppet, dc=example, dc=com in their DN.

This setting is optional. If you choose not to set it, PE searches for the user in the base DN (example: ou=Puppet, dc=example, dc=com). Setting a user RDN is helpful in the following situations:

- When you experience long wait times for operations that contact the directory service (either when logging in or importing a group for the first time). Specifying a user RDN reduces the number of entries that are searched.
- When you have more than one entry under your base DN with the same login value.

**Tip:** It is not currently possible to specify multiple user RDNs. If you want to filter RDNs when constructing your query, we suggest creating a new lookup user who only has read access for the users and groups you want to use in PE.

**Group object class** The name of an object class that all groups have.

**Group membership field** Tells PE how to find which users belong to which groups. This is the name of the attribute in the external directory groups that indicates who the group members are.

**Group name attribute** The attribute that stores the display name for groups. This is used for display purposes only.

**Group lookup attribute** The value used to import groups into PE. Given the example directory service entry provided above, the group lookup attribute would be cn. When specifying the Inspectors group in the console to import it, provide the name inspectors.

The value for this attribute must be unique under your search base. If you have users with the same login as the lookup of a group that you want to use, you can narrow the search base, use a value for the lookup attribute that you know to be unique, or specify the **Group object class** that all of your groups have in common but your users do not.

**Tip:** If you have a large number of nested groups in your group hierarchy, or you experience slowness when logging in with RBAC, we recommend disabling nested group search unless you need it for your authorization schema to work.

**Group relative distinguished name (optional)** The group RDN that you set here is concatenated with the base DN to form the search base when looking up a group. For example, if you specify ou=groups for the group RDN, and your base DN setting is ou=Puppet, dc=example, dc=com, PE finds groups that have ou=groups, ou=Puppet, dc=example, dc=com in their DN.

This setting is optional. If you choose not to set it, PE searches for the group in the base DN (example: ou=Puppet, dc=example, dc=com). Setting a group RDN is helpful in the following situations:

- When you experience long wait times for operations that contact the directory service (either when logging in or importing a group for the first time). Specifying a group RDN reduces the number of entries that are searched.
- When you have more than one entry under your base DN with the same lookup value.

**Tip:** It is not currently possible to specify multiple group RDNs. If you want to filter RDNs when constructing your query, create a new lookup user who only has read access for the users and groups you plan to use in PE.

**Note:** At present, PE supports only a single Base DN. Use of multiple user RDNs or group RDNs is not supported.

**Turn off LDAP_MATCHING_RULE_IN_CHAIN?** Select Yes to turn off the LDAP matching rule that looks up the chain of ancestry for an object until it finds a match. For organizations with a large number of group memberships, matching rule in chain can slow performance.

**Search nested groups?** Select Yes to search for groups that are members of an external directory group. For organizations with a large number of nested group memberships, searching nested groups can slow performance.

**Related information**

PUT /ds on page 231
Replaces current directory service connection settings. Authentication is required.

**Verify directory server certificates**

To ensure that RBAC isn't being subjected to a Man-in-the Middle (MITM) attack, verify the directory server's certificate.

When you select SSL or StartTLS as the security protocol to use for communications between PE and your directory server, the connection to the directory is encrypted. To ensure that the directory service is properly identified, configure the `ds-trust-chain` to point to a copy of the public key for the directory service.

The RBAC service verifies directory server certificates using a trust store file, in Java Key Store (JKS), PEM, or PKCS12 format, that contains the chain of trust for the directory server's certificate. This file needs to exist on disk in a location that is readable by the user running the RBAC service.

To turn on verification:

1. In the console, click **Node groups**.
2. Open the **PE Infrastructure** node group and select the **PE Console** node group.
3. Click **Classes**. Locate the `puppet_enterprise::profile::console` class.
4. In the **Parameter** field, select `rbac_ds_trust_chain`.
5. In the **Value** field, set the absolute path to the trust store file.
6. Click **Add parameter**, and commit changes.
7. To make the change take effect, run Puppet. Running Puppet restarts pe-console-services.

After this value is set, the directory server's certificate is verified whenever RBAC is configured to connect to the directory server using SSL or StartTLS.

**Enable custom password policies through LDAP**

Password policies are not configurable in PE. However, if your organization requires more complex password policies than the default, you can allow LDAP to manage custom password policies by delegating administrative privileges to LDAP and then revoking the admin user in the console.

**Before you begin**

Enable LDAP by [Connecting external directory services to PE](#) on page 201. Make sure you are logged into LDAP as the administrative user and have given LDAP administrative privileges.

Revoke the admin user:

1. In the console, on the **Access control** page, click the **Users** tab.
2. Select **Administrator**.
3. On the **User details** page, click **Revoke user access**.

You have revoked the admin user in the console, which allows LDAP to manage password policies. To enable the admin again, select **Reinstate user access** on the admin's **User details** page.

**Working with user groups from an external directory service**

You don’t explicitly add remote users to PE. Instead, after the external directory service has been successfully connected, remote users must log into PE, which creates their user record.

If the user belongs to an external directory group that has been imported into PE and then assigned to a role, the user is assigned to that role and gains the privileges of the role. Roles are additive: You can assign users to more than one role, and they gain the privileges of all the roles to which they are assigned.
Import a user group from an external directory service
You import existing external directory groups to PE explicitly, which means you add the group by name.

1. In the console, on the Access control page, click the User groups tab.
   User groups is available only if you have established a connection with an external directory.
2. In the Login field, enter the name of a group from your external directory.
3. Click Add group.
   Remember: No user roles are listed until you add this group to a role. No users are listed until a user who
   belongs to this group logs into PE.

Troubleshooting: A PE user and user group have the same name
If you have both a PE user and an external directory user group with the exact same name, PE throws an error when
you try to log on as that user or import the user group.

To work around this problem, you can change your settings to use different RDNs for users and groups. This works as
long as all of your users are contained under one RDN that is unique from the RDN that contains all of your groups.

Assign a user group to a user role
After you’ve imported a group, you can assign it a user role, which gives each group member the permissions
associated with that role. You can add user groups to existing roles, or you can create a new role, and then add the
group to the new role.

1. In the console, on the Access control page, click the User roles tab.
2. Click the role you want to add the user group to.
3. Click Member groups. In the Group name field, select the user group you want to add to the user role.
4. Click Add group, and commit changes.

Delete a user group
You can delete a user group in the console. Users who were part of the deleted group lose the permissions associated
with roles assigned to the group.

Remember: This action removes the group only from Puppet Enterprise, not from the associated external directory
service.

1. In the console, on the Access control page, click the User groups tab.
   User groups is available only if you have established a connection with an external directory.
2. Locate the group that you wish to delete.
3. Click Remove.

Removing a remote user’s access to PE
In order to fully revoke the remote user’s access to Puppet Enterprise, you must also remove the user from the
external directory groups accessed by PE.

Deleting a remote user’s PE account does not automatically prevent that user from accessing PE in the future. So long
as the remote user is still a member of a group in an external directory that PE is configured to access, the user retains
the ability to log into PE.

If you delete a user from your external directory service but not from PE, the user can no longer log in, but any
generated tokens or existing console sessions continue to be valid until they expire. To invalidate the user’s tokens or
sessions, revoke the user’s PE account, which also automatically revokes all tokens for the user. You must manually
delete the user for their account record to disappear.

© 2020 Puppet, Inc.
Token-based authentication

Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric “token” to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

You can generate authentication tokens using puppet-access or the RBAC API V2 endpoint. You can also generate one-off tokens that do not need to be saved, which are typically used by a service.

RBAC settings for authentication tokens can be managed in the console in the PE Infrastructure group. See Configure RBAC and token-based authentication settings on page 163 for a list of settings you can change.

Authentication tokens manage access to the following PE services:

- Puppet orchestrator
- Code Manager
- Node classifier
- Role-based access control (RBAC)
- Activity service
- PuppetDB

Related information

Installing PE client tools on page 129
PE client tools are a set of command line tools that let you access Puppet Enterprise services from a workstation that might or might not be managed by Puppet.

User permissions on page 195
The table below lists the available object types and their permissions, as well as an explanation of the permission and how to use it.

Configure puppet-access

The puppet-access command allows users to generate and manage authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master. Ensure puppet-access is configured correctly before using it to generate authentication tokens.

The configuration file for puppet-access allows you to generate tokens from the CLI without having to pass additional flags.

Whether you are running puppet-access on a PE-managed server or installing it on a separate workstation, you need a global configuration file and a user-specified configuration file.

Global configuration file

The global configuration file is located at:

- **On *nix systems:** /etc/puppetlabs/client-tools/puppet-access.conf
- **On Windows systems:** C:/ProgramData/PuppetLabs/client-tools/puppet-access.conf

On machines managed by Puppet Enterprise, this global configuration file is created for you. The configuration file is formatted in JSON. For example:

```json
{
    "service-url": "https://<CONSOLE HOSTNAME>:4433/rbac-api",
    "token-file": "~/.puppetlabs/token",
    "certificate-file": "/etc/puppetlabs/puppet/ssl/certs/ca.pem"
}
```

PE determines and adds the service-url setting.
If you're running `puppet-access` from a workstation not managed by PE, you must create the global file and populate it with the configuration file settings.

**User-specified configuration file**

The user-specified configuration file is located at `~/.puppetlabs/client-tools/puppet-access.conf` for both *nix and Windows systems. You must create the user-specified file and populate it with the configuration file settings. A list of configuration file settings is found in the next section.

The user-specified configuration file always takes precedence over the global configuration file. For example, if the two files have contradictory settings for the `token-file`, the user-specified settings prevail.

**Important:** User-specified configuration files must be in JSON format; HOCON and INI-style formatting are not supported.

**Configuration file settings for puppet-access**

As needed, you can manually add configuration settings to your user-specified or global `puppet-access` configuration file.

The class that manages the global configuration file is `puppet_enterprise::profile::controller`.

You can also change configuration settings by specifying flags when using the `puppet-access` command in the command line.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
<th>Command line flag</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>token-file</code></td>
<td>The location for storing authentication tokens. Defaults to <code>~/.puppetlabs/token</code>.</td>
<td><code>-t,--token-file</code></td>
</tr>
<tr>
<td><code>certificate-file</code></td>
<td>The location of the CA that signed the console-services server's certificate. Defaults to the PE CA cert location, <code>/etc/puppetlabs/puppet/ssl/certs/ca.pem</code>.</td>

</tbody>
</table>

**Generate a token using puppet-access**

Use `puppet-access` to generate an authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master.

**Before you begin**

Install the PE client tools package and configure `puppet-access`. 

© 2020 Puppet, Inc.
1. Choose one of the following options, depending on how long you need your token to last:
   - To generate a token with the default one-hour lifetime, run `puppet-access login`.
   - To generate a token with a specific lifetime, run `puppet-access login --lifetime <TIME PERIOD>`.
     
     For example, `puppet-access login --lifetime 5h` generates a token that lasts five hours.

2. When prompted, enter the same username and password that you use to log into the PE console.

   The `puppet-access` command contacts the token endpoint in the RBAC v1 API. If your login credentials are correct, the RBAC service generates a token.

3. The token is generated and stored in a file for later use. The default location for storing the token is `~/.puppetlabs/token`. You can print the token at any time using `puppet-access show`.

   You can continue to use this token until it expires, or until your access is revoked. The token has the exact same set of permissions as the user that generated it.

   **CAUTION:** If you run the login command with the `--debug` flag, the client outputs the token, as well as the username and password. For security reasons, exercise caution when using the `--debug` flag with the login command.

**Note:** If a remote user generates a token and then is deleted from your external directory service, the deleted user cannot log into the console. However, because the token has already been authenticated, the RBAC service does not contact the external directory service again when the token is used in the future. To fully remove the token’s access, you need to manually revoke or delete the user from PE.

**Related information**

- [Setting a token-specific lifetime on page 212](#)

  Tokens have a default lifetime of one hour, but you can set a different lifetime for your token when you generate it. This allows you to keep one token for multiple sessions.

**Generate a token using the API endpoint**

The RBAC v1 API includes a token endpoint, which allows you to generate a token using curl commands.

1. On the command line, post your RBAC user login credentials using the token endpoint.

   **Bash**

   ```bash
type_header='Content-Type: application/json'
uri="https://$(puppet config print server):4433/rbac-api/v1/auth/token"
data='{"login": "<USER>",
     "password": "<PASSWORD>"}"
curl --insecure --header "$type_header" --request POST "$uri" --data "$data"
```

   The command returns a JSON object containing the key `token` and the token itself.

   **CAUTION:** If you are using curl commands with the `--k` or `--insecure` SSL connection options, keep in mind that you are vulnerable to a person-in-the-middle attack.

2. Save the token. Depending on your workflow, either:
   - Copy the token to a text file.
   - Save the token as an environment variable using `export TOKEN=<PASTE THE TOKEN HERE>`.

   You can continue to use this token until it expires, or until your access is revoked. The token has the exact same set of permissions as the user that generated it.

**Note:** If a remote user generates a token and then is deleted from your external directory service, the deleted user cannot log into the console. However, because the token has already been authenticated, the RBAC service does not contact the external directory service again when the token is used in the future. To fully remove the token’s access, you need to manually revoke or delete the user from PE.
contact the external directory service again when the token is used in the future. To fully remove the token's access, you need to manually revoke or delete the user from PE.

**Use a token with the PE API endpoints**
The example below shows how to use a token in an API request. In this example, you use the /users/current endpoint of the RBAC v1 API to get information about the current authenticated user.

**Before you begin**
Generate a token using `puppet-access login`.

Run the following commands:

```bash
curl --insecure --header "X-Authentication: $(puppet-access show)" https://$(puppet config print server):4433/rbac-api/v1/users/current

auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/rbac-api/v1/users/current"

curl --insecure --header "$auth_header" "$uri"
```

The commands above uses the X-Authentication header to supply the token information.

In some cases, such as GitHub webhooks, you might need to supply the token in a token parameter by specifying the request as follows:

```bash
uri="https://$(puppet config print server):4433/rbac-api/v1/users/current?token=$(puppet-access show)"

curl --insecure "$uri"
```

⚠️ **CAUTION:** If you are using curl commands with the `--k` or `--insecure` SSL connection options, keep in mind that you are vulnerable to a person-in-the-middle attack.

**Generate a token for use by a service**
If you need to generate a token for use by a service and the token doesn't need to be saved, use the `--print` option.

**Before you begin**
Install the PE client tools package and configure `puppet-access`.

Run `puppet-access login [username] --print`.

This command generates a token, and then displays the token content as stdout (standard output) rather than saving it to disk.

**Tip:** When generating a token for a service, consider specifying a longer token lifetime so that you don't have to regenerate the token too frequently.

**Change the token's default lifetime**
Tokens have a default authentication lifetime of one hour, but this default value can be adjusted in the console. You can also change a token's maximum authentication lifetime, which defaults to 10 years.

1. In the console, click **Node groups**.
2. Open the **PE Infrastructure** node group and click the **PE Console** node group.
3. On the **Classes** tab, find the `puppet_enterprise::profile::console` class.
4. In the **Parameter** field, select `rbac_token_auth_lifetime` to change the default lifetime of all tokens, or `rbac_token_maximum_lifetime` to adjust the maximum allowable lifetime for all tokens.
5. In the **Value** field, enter the new default authentication lifetime.
   Specify a numeric value followed by "y" (years), "d" (days), "h" (hours), "m" (minutes), or "s" (seconds). For example, "12h" generates a token valid for 12 hours.
   Do not add a space between the numeric value and the unit of measurement. If you do not specify a unit, it is assumed to be seconds.
   The `rbac_token_auth_lifetime` cannot exceed the `rbac_token_maximum_lifetime` value.

6. Click **Add parameter**, and commit changes.

### Setting a token-specific lifetime

Tokens have a default lifetime of one hour, but you can set a different lifetime for your token when you generate it. This allows you to keep one token for multiple sessions.

Specify a numeric value followed by "y" (years), "d" (days), "h" (hours), "m" (minutes), or "s" (seconds). For example, "12h" generates a token valid for 12 hours.

Do not add a space between the numeric value and the unit of measurement. If you do not specify a unit, it is assumed to be seconds.

Use the `--lifetime` parameter if using `puppet-access` to generate your token. For example: `puppet-access login --lifetime 1h`.

Use the `lifetime` value if using the RBAC v1 API to generate your token. For example: `{"login": "<YOUR PE USER NAME>", "password": "<YOUR PE PASSWORD>", "lifetime": "1h"}`.

### Change account expiration settings

In addition to token lifetime defaults, you can also activate and change the user account expiration and idle user settings.

#### account-expiry-days

This parameter is a positive integer that specifies the duration, in days, before an inactive user account expires. The default value is undefined.

If a non-superuser hasn’t logged into the console during this specified period, their user status updates to revoked.

After creating an account, if a non-superuser hasn’t logged in to the console during the specified period, their user status updates to revoked.

**Important:** If the `account-expiry-days` parameter is not specified, or has a value of less than 1, the `account-expiry-check-minutes` parameter is ignored.

To activate this setting in the console, add a value of 1 (day) or greater to the `account_expire_days` parameter in the `puppet_enterprise::profile::console` class of the **PE Infrastructure** group.

#### account-expiry-check-minutes

This parameter is a positive integer that specifies how often, in minutes, the application checks for idle user accounts. The default value is 60 minutes.

To change this setting in the console, set a value (in minutes) for the `account_expiry_check_minutes` parameter in the `puppet_enterprise::profile::console` class of the **PE Infrastructure** group.

For more information on configuration options, or to use a different configuration method for changing settings, see the [Methods for configuring Puppet Enterprise](#) on page 151.
Set a token-specific label

You can affix a plain-text, user-specific label to tokens you generate with the RBAC v1 API. Token labels allow you to more readily refer to your token when working with RBAC API endpoints, or when revoking your own token.

Token labels are assigned on a per-user basis: two users can each have a token labelled “my token”, but a single user cannot have two tokens both labelled “my token.” You cannot use labels to refer to other users’ tokens.

Generate a token using the token endpoint of the RBAC API, using the label value to specify the name of your token.

```json
{"login": "<YOUR PE USER NAME>", "password": "<YOUR PE PASSWORD>", "label": "Ava's token"}
```

Labels must be no longer than 200 characters, must not contain commas, and must contain something besides whitespace.

View token activity

Token activity is logged by the activity service. You can see recent token activity on any user's account in the console.

1. In the console, on the Access control page, click the Users tab and select the full name of the user you are interested in.
2. Click the Activity tab.

Revoking a token

Revoke tokens by username, label, or full token through the token endpoint of the v2 RBAC API. All token revocation attempts are logged in the activity service, and can be viewed on the user's Activity tab in the console.

You can revoke your own token by username, label, or full token. You can also revoke any other full token you possess. Users with the permission to revoke other users can also revoke those users' tokens, as the users:disable permission includes token revocation. Revoking a user's tokens does not revoke the user's PE account.

If a user's account is revoked, all tokens associated with that user account are also automatically revoked.

Delete a token file

If you logged into puppet-access to generate a token, you can remove the file that stores that token simply by running the delete-token-file command. This is useful if you are working on a server that is used by other people.

Deleting the token file prevents other users from using your authentication token, but does not actually revoke the token. After the token has expired, there's no risk of obtaining the contents of the token file.

From the command line, run one of the following commands, depending on the path to your token file:

- If your token is at the default token file location, run `puppet-access delete-token-file`.
- If you used a different path to store your token file, run `puppet-access delete-token-file --token-path <YOUR TOKEN PATH>`.

RBAC API v1

The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.
Endpoints on page 214
The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.

Forming RBAC API requests on page 215
Token-based authentication is required to access the RBAC API. You can authenticate requests by using either user authentication tokens or whitelisted certificates.

Users endpoints on page 216
RBAC enables you to manage local users as well as those who are created remotely, on a directory service. With the users endpoints, you can get lists of users and create new local users.

User group endpoints on page 220
Groups are used to assign roles to a group of users, which is vastly more efficient than managing roles for each user individually. The groups endpoints enable you to get lists of groups, and to add a new directory group.

User roles endpoints on page 223
By assigning roles to users, you can manage them in sets that are granted access permissions to various PE objects. This makes tracking user access more organized and easier to manage. The roles endpoints enable you to get lists of roles and create new roles.

Permissions endpoints on page 226
You assign permissions to user roles to manage user access to objects. The permissions endpoints enable you to get information about available objects and the permissions that can be constructed for those objects.

Token endpoints on page 228
A user’s access to PE services can be controlled using authentication tokens. Users can generate their own authentication tokens using the token endpoint.

Directory service endpoints on page 230
Use the ds (directory service) API endpoints to get information about the directory service, test your directory service connection, and replace directory service connection settings.

Password endpoints on page 232
When local users forget passwords or lock themselves out of PE by attempting to log in with incorrect credentials too many times, you must generate a password reset token for them. The password endpoints enable you to generate password reset tokens for a specific local user or with a token that contains a temporary password in the body.

RBAC service errors on page 234
You’re likely to encounter some errors when using the RBAC API. You’ll want to familiarize yourself with the error response descriptions and the general error responses.

Configuration options on page 236
There are various configuration options for the RBAC service. Each section can exist in its own file or in separate files.

**Related information**

API index on page 33
APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

## Endpoints

The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.

For general information about forming HTTP requests to the API, see the forming requests page. For information on errors encountered while using the RBAC v1 API, see the RBAC service errors page.

**Tip:** In addition to the endpoints on this page and in the v2 RBAC service API, there are endpoints that you can use to check the health of the RBAC service. These are available through the status API documentation.

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>users</td>
<td>Manage local users as well as those from a directory service, get lists of users, and create new local users.</td>
</tr>
<tr>
<td>groups</td>
<td>Get lists of groups and add a new remote user group.</td>
</tr>
<tr>
<td>roles</td>
<td>Get lists of user roles and create new roles.</td>
</tr>
</tbody>
</table>
## Forming RBAC API requests

Token-based authentication is required to access the RBAC API. You can authenticate requests by using either user authentication tokens or whitelisted certificates.

By default, the RBAC service listens on port 4433. All endpoints are relative to the `/rbac-api/` path. So, for example, the full URL for the `/v1/users` endpoint on localhost is `https://localhost:4433/rbac-api/v1/users`.

### Authentication using tokens

Insert a user authentication token in an RBAC API request.

1. Generate a token: `puppet-access login`
2. Print the token and copy it: `puppet-access show`
3. Save the token as an environment variable: `export TOKEN=<PASTE THE TOKEN HERE>`
4. Include the token variable in your API request:

   **Bash**
   ```bash
   auth_header="X-Authentication: $(puppet-access show)"
   uri="https://$(puppet config print print server):4433/rbac-api/v1/users/current"
   curl --insecure --header "$auth_header" "$uri"
   ```

   The example above uses the X-Authentication header to supply the token information. In some cases, such as GitHub webhooks, you might need to supply the token in a token parameter. To supply the token in a token parameter, specify the request as follows:

   **Bash**
   ```bash
   uri="https://$(puppet config print print server):4433/rbac-api/v1/users/current?token=$(puppet-access show)"
   curl --insecure "$uri"
   ```

   **CAUTION:** Be aware when using the token parameter method that the token parameter might be recorded in server access logs.

### Authentication using whitelisted certificate

You can also authenticate requests using a certificate listed in RBAC's certificate whitelist, located at `/etc/puppetlabs/console-services/rbac-certificate-whitelist`. Note that if you edit this file, you must reload the `pe-console-services` service (run `sudo service pe-console-services reload`) for your changes to take effect.

---

© 2020 Puppet, Inc.
Attach the certificate using the command line, as demonstrated in the example curl query below. You must have the whitelisted certificate name (which must match a name in the /etc/puppetlabs/console-services/rbac-certificate-whitelist file) and the private key to run the script.

**Bash**

```bash
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/rbac-api/v1/users/current"
curl --cert "$cert" --cacert "$cacert" --key "$key" "$uri"
```

You do not need to use an agent certificate for authentication. You can use `puppet cert generate` to create a new certificate specifically for use with the API.

**Related information**

[Token-based authentication](#) on page 208

Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

**Content-type headers in the RBAC API**

RBAC accepts only JSON payloads in PUT and POST requests.

If a payload is provided, it is important to specify that the content is in JSON format. Thus, all PUT and POST requests with non-empty bodies should have the `Content-Type` header set to `application/json`.

**Users endpoints**

RBAC enables you to manage local users as well as those who are created remotely, on a directory service. With the users endpoints, you can get lists of users and create new local users.

**Users keys**

The following keys are used with the RBAC v1 API's users endpoints.

<table>
<thead>
<tr>
<th>Key</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>A UUID string identifying the user.</td>
<td>&quot;4fee7450-54c7-11e4-916c-0800200c9a66&quot;</td>
</tr>
<tr>
<td>login</td>
<td>A string used by the user to log in. Must be unique among users and groups.</td>
<td>&quot;admin&quot;</td>
</tr>
<tr>
<td>email</td>
<td>An email address string. Not currently utilized by any code in PE.</td>
<td>&quot;<a href="mailto:hill@example.com">hill@example.com</a>&quot;</td>
</tr>
<tr>
<td>display_name</td>
<td>The user's name as a string.</td>
<td>&quot;Kalo Hill&quot;</td>
</tr>
<tr>
<td>role_ids</td>
<td>An array of role IDs indicating which roles should be directly assigned to</td>
<td>[3 6 5]</td>
</tr>
<tr>
<td>is_group</td>
<td>These flags indicate the type of user. is_group should always be false</td>
<td>true/false</td>
</tr>
<tr>
<td>is_remote</td>
<td>for a user.</td>
<td>true/false</td>
</tr>
<tr>
<td>is_superuser</td>
<td></td>
<td>true/false</td>
</tr>
<tr>
<td>is_revoked</td>
<td>Setting this flag to true prevents the user from accessing any routes</td>
<td>true/false</td>
</tr>
<tr>
<td></td>
<td>until the flag is unset or the user's password is reset via token.</td>
<td></td>
</tr>
</tbody>
</table>

### Key

<table>
<thead>
<tr>
<th>Key</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>last_login</td>
<td>This is a timestamp in UTC-based ISO-8601 format (YYYY-MM-DDThh:mm:ssZ) indicating when the user last logged in. If the user has never logged in, this value is null.</td>
<td>&quot;2014-05-04T02:32:00Z&quot;</td>
</tr>
<tr>
<td>inherited_role_ids</td>
<td>An array of role IDs indicating which roles a remote user inherits from their groups.</td>
<td>[9 1 3]</td>
</tr>
<tr>
<td>group_ids</td>
<td>An array of UUIDs indicating which groups a remote user inherits roles from.</td>
<td>[&quot;3a96d280-54c9-11e4-916c-0800200c9a66&quot;]</td>
</tr>
</tbody>
</table>

### GET /users

Fetches all users, both local and remote (including the superuser). Supports filtering by ID through query parameters. Authentication is required.

**Request format**

To request all the users:

```
GET /users
```

To request specific users, add a comma-separated list of user IDs:

```
GET /users?
id=fe62d770-5886-11e4-8ed6-0800200c9a66,1cadd0e0-5887-11e4-8ed6-0800200c9a66
```

**Response format**

The response is a JSON object that lists the metadata for all requested users.

For example:

```
[
  {
    "id": "fe62d770-5886-11e4-8ed6-0800200c9a66",
    "login": "Kalo",
    "email": "kalohill@example.com",
    "display_name": "Kalo Hill",
    "role_ids": [1,2,3...],
    "is_group": false,
    "is_remote": false,
    "is_superuser": true,
    "is_revoked": false,
    "last_login": "2014-05-04T02:32:00Z"
  },
  {
    "id": "07d9c8e0-5887-11e4-8ed6-0800200c9a66",
    "login": "Jean",
    "email": "jeanjackson@example.com",
    "display_name": "Jean Jackson",
    "role_ids": [2,3],
    "inherited_role_ids": [5],
    "is_group": false,
    "is_remote": true,
    "is_superuser": false,
    "group_ids": ["2ca57e30-5887-11e4-8ed6-0800200c9a66"],
    "is_revoked": false,
    "last_login": "2014-05-04T02:32:00Z"
  }
]
```
GET /users/<sid>
Fetches a single user by its subject ID (sid). Authentication is required.

Response format
For all users, the user contains an ID, a login, an email, a display name, a list of role-ids the user is directly assigned to, and the last login time in UTC-based ISO-8601 format (YYYY-MM-DDThh:mm:ssZ), or null if the user has not logged in yet. It also contains an "is_revoked" field, which, when set to true, prevents a user from authenticating.

For example:
```
{"id": "fe62d770-5886-11e4-8ed6-0800200c9a66",
"login": "Amari",
"email": "amariperez@example.com",
"display_name": "Amari Perez",
"role_ids": [1, 2, 3...],
"is_group" : false,
"is_remote" : false,
"is_superuser" : false,
"is_revoked": false,
"last_login": "2014-05-04T02:32:00Z"}
```

For remote users, the response additionally contains a field indicating the IDs of the groups the user inherits roles from and the list of inherited role IDs.

For example:
```
{"id": "07d9c8e0-5887-11e4-8ed6-0800200c9a66",
"login": "Jean",
"email": "jeanjackson@example.com",
"display_name": "Jean Jackson",
"role_ids": [2, 3...],
"inherited_role_ids": [ ],
"is_group" : false,
"is_remote" : true,
"is_superuser" : false,
"group_ids": ["b28b8790-5889-11e4-8ed6-0800200c9a66"],
"is_revoked": false,
"last_login": "2014-05-04T02:32:00Z"}
```
**GET /users/current**
Fetcheds the data about the current authenticated user, with the exact same behavior as GET /users/<sid>, except that <sid> is assumed from the authentication context. Authentication is required.

**POST /users**
Creates a new local user. You can add the new user to user roles by specifying an array of roles in role_ids. You can set a password for the user in password. For the password to work in the PE console, it needs to be a minimum of six characters. Authentication is required.

**Request format**
Accepts a JSON body containing entries for email, display_name, login, role_ids, and password. The password field is optional. The created account is not useful until the password is set.

For example:

```json
{"login": "Kalo",
 "email": "kalohill@example.com",
 "display_name": "Kalo Hill",
 "role_ids": [1,2,3],
 "password": "yabbadabba"}
```

**Response format**
If the create operation is successful, a 201 Created response with a location header that points to the new resource is returned.

**Error responses**
If the email or login for the user conflicts with an existing user's login, a 409 Conflict response is returned.

**PUT /users/<sid>**
Replaces the user with the specified ID (sid) with a new user object. Authentication is required.

**Request format**
Accepts an updated user object with all keys provided when the object is received from the API. The behavior varies based on user type. All types have a role_id array that indicates all the roles the user should belong to. An empty roles array removes all roles directly assigned to the group.

The below examples show what keys must be submitted. Keys marked with asterisks are the only ones that can be changed via the API.

An example for a local user:

```json
{"id": "c8b2c380-5889-11e4-8ed6-0800200c9a66",
 **"login": "Amari",
 **"email": "amariperez@example.com",
 **"display_name": "Amari Perez",
 **"role_ids": [1, 2, 3],
 "is_group": false,
 "is_remote": false,
 "is_superuser": false,
 **"is_revoked": false,
 "last_login": "2014-05-04T02:32:00Z"}
```

An example for a remote user:

```json
{"id": "3271fde0-588a-11e4-8ed6-0800200c9a66",
 "login": "Jean",
```
"email": "jeanjackson@example.com",
"display_name": "Jean Jackson",
"role_ids": [4, 1],
"inherited_role_ids": [],
"group_ids": [],
"is_group": false,
"is_remote": true,
"is_superuser": false,
"is_revoked": false,
"last_login": "2014-05-04T02:32:00Z"

Response format
The request returns a 200 OK response, along with the user object with the changes made.

Error responses
If the login for the user conflicts with an existing user login, a 409 Conflict response is returned.

DELETE /users/<sid>
Deletes the user with the specified ID (sid), regardless of whether they are a user defined in RBAC or a user defined by a directory service. In the case of directory service users, while this action removes a user from the console, that user is still able to log in (at which point they are re-added to the console) if they are not revoked. Authentication is required.

Remember: The admin user and the api_user cannot be deleted.

Request format
For example, to delete a user with the ID 3982a629-1278-4e38-883e-12a7cac91535 by using a curl command:

Bash

cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
url="https://$(puppet config print server):4433/rbac-api/v1/users/3982a629-1278-4e38-883e-12a7cac91535"
curl --cert "$cert" --cacert "$cacert" --key "$key" --request DELETE "$url"

Response format
If the user is successfully deleted, a 204 No Content response with an empty body is returned.

Error responses
If the current user does not have the users:edit permission for this user group, a 403 Forbidden response is returned.

If a user with the provided identifier does not exist, a 404 Not Found response is returned.

User group endpoints
Groups are used to assign roles to a group of users, which is vastly more efficient than managing roles for each user individually. The groups endpoints enable you to get lists of groups, and to add a new directory group.

Remember: Group membership is determined by the directory service hierarchy and as such, local users cannot be in directory groups.
User group keys
The following keys are used with the RBAC v1 API's groups endpoints.

<table>
<thead>
<tr>
<th>Key</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>A UUID string identifying the group.</td>
<td>&quot;c099d420-5557-11e4-916c-0800200c9a66&quot;</td>
</tr>
<tr>
<td>login</td>
<td>the identifier for the user group on the directory server.</td>
<td>&quot;poets&quot;</td>
</tr>
<tr>
<td>display_name</td>
<td>The group's name as a string.</td>
<td>&quot;Poets&quot;</td>
</tr>
<tr>
<td>role_ids</td>
<td>An array of role IDs indicating which roles should be inherited by the group's members. An empty array is valid. This is the only field that can be updated via RBAC; the rest are immutable or synced from the directory service.</td>
<td>[3 6 5]</td>
</tr>
<tr>
<td>is_group</td>
<td>These flags indicate that the group is a group.</td>
<td>true, true, false, respectively</td>
</tr>
<tr>
<td>is_remote</td>
<td></td>
<td></td>
</tr>
<tr>
<td>is_superuser</td>
<td></td>
<td></td>
</tr>
<tr>
<td>is_revoked</td>
<td>Setting this flag to true currently does nothing for a group.</td>
<td>true/false</td>
</tr>
<tr>
<td>user_ids</td>
<td>An array of UUIDs indicating which users inherit roles from this group.</td>
<td>[&quot;3a96d280-54c9-11e4-916c-0800200c9a66&quot;]</td>
</tr>
</tbody>
</table>

GET /groups
Fetched all groups. Supports filtering by ID through query parameters. Authentication is required.

Request format
The following requests all the groups:

    GET /groups

To request only some groups, add a comma-separated list of group IDs:

    GET /groups?
    id=65a068a0-588a-11e4-8ed6-0800200c9a66,75370a30-588a-11e4-8ed6-0800200c9a66

Response format
The response is a JSON object that lists the metadata for all requested groups.

For example:

```json
[
    {
        "id": "65a068a0-588a-11e4-8ed6-0800200c9a66",
        "login": "hamsters",
        "display_name": "Hamster club",
        "role_ids": [2, 3],
        "is_group": true,
        "is_remote": true,
        "is_superuser": false,
        "user_ids": ["07d9c8e0-5887-11e4-8ed6-0800200c9a66"]
    },
```
"id": "75370a30-588a-11e4-8ed6-0800200c9a66",
"login": "chinchilla",
"display_name": "Chinchilla club",
"role_ids": [2, 1],
"is_group": true,
"is_remote": true,
"is_superuser": false,
"user_ids": [
"1cadd0e0-5887-11e4-8ed6-0800200c9a66",
"5c1ab4b0-588b-11e4-8ed6-0800200c9a66"
],
{"id": "ccdbde50-588a-11e4-8ed6-0800200c9a66",
"login": "wombats",
"display_name": "Wombat club",
"role_ids": [2, 3],
"is_group": true,
"is_remote": true,
"is_superuser": false,
"user_ids": []
}

GET /groups/<sid>
Fetches a single group by its subject ID (sid). Authentication is required.

Response format
The response contains an ID for the group and a list of role_ids the group is directly assigned to.

For directory groups, the response contains the display name, the login field, a list of role_ids directly assigned to the group, and user_ids containing IDs of the remote users that belong to that group.

For example:

{"id": "65a068a0-588a-11e4-8ed6-0800200c9a66",
"login": "hamsters",
"display_name": "Hamster club",
"role_ids": [2, 3],
"is_group": true,
"is_remote": true,
"is_superuser": false,
"user_ids": ["07d9c8e0-5887-11e4-8ed6-0800200c9a66"]
}

Error responses
If the user who submits the GET request has not successfully authenticated, a 401 Unauthorized response is returned.
If the current user does not have the appropriate user permissions to request the group data, a 403 Forbidden response is returned.

POST /groups
Creates a new remote group and attaches to the new group any roles specified in its roles list. Authentication is required.

Request format
Accepts a JSON body containing an entry for login, and an array of role_ids to assign to the group initially.

For example:

{"login": "Augmentators",
"role_ids": [1, 2, 3]}
Response format
If the create operation is successful, a 201 Created response with a location header that points to the new resource is returned.

Error responses
If the login for the group conflicts with an existing group login, a 409 Conflict response is returned.

PUT /groups/<sid>
Replaces the group with the specified ID (sid) with a new group object. Authentication is required.

Request format
Accepts an updated group object containing all the keys that were received from the API initially. The only updatable field is role_ids. An empty roles array indicates a desire to remove the group from all the roles it was directly assigned to. Any other changed values are ignored.

For example:
```json
{
    "id": "75370a30-588a-11e4-8ed6-0800200c9a66",
    "login": "chinchilla",
    "display_name": "Chinchillas",
    "role_ids": [2, 1],
    "is_group": true,
    "is_remote": true,
    "is_superuser": false,
    "user_ids": [
    "1cadd0e0-5887-11e4-8ed6-0800200c9a66",
    "5c1ab4b0-588b-11e4-8ed6-0800200c9a66"
    ]
}
```

Response format
If the operation is successful, a 200 OK response including a group object with updated roles is returned.

DELETE /groups/<sid>
Deletes the user group with the specified ID (sid) from RBAC without making any changes to the directory service. Authentication required.

Response format
If the user group is successfully deleted, a 204 No Content with an empty body is returned.

Error responses
If the current user does not have the user_groups:delete permission for this user group, a 403 Forbidden response is returned.
If a group with the provided identifier does not exist, a 404 Not Found response is returned.

User roles endpoints
By assigning roles to users, you can manage them in sets that are granted access permissions to various PE objects. This makes tracking user access more organized and easier to manage. The roles endpoints enable you to get lists of roles and create new roles.

User role keys
The following keys are used with the RBAC v1 API’s roles endpoints.

<table>
<thead>
<tr>
<th>Key</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An integer identifying the role.</td>
<td>18</td>
</tr>
<tr>
<td>Key</td>
<td>Explanation</td>
<td>Example</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>display_name</td>
<td>The role's name as a string.</td>
<td>&quot;Viewers&quot;</td>
</tr>
<tr>
<td>description</td>
<td>A string describing the role's function.</td>
<td>&quot;View-only permissions&quot;</td>
</tr>
<tr>
<td>permissions</td>
<td>An array containing permission objects that indicate what permissions a role grants. An empty array is valid. See Permission keys for more information.</td>
<td>[]</td>
</tr>
<tr>
<td>user_ids</td>
<td>An array of UUIDs indicating which users and groups are directly assigned to the role. An empty array is valid.</td>
<td>[&quot;fc115750-555a-11e4-916c-0800200c9a66&quot;]</td>
</tr>
<tr>
<td>group_ids</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**GET /roles**

Fetched all roles with user and group ID lists and permission lists. Authentication is required.

**Response format**

Returns a JSON object containing all roles with user and group ID lists and permission lists.

For example:

```json
[{ "id": 123,    
  "permissions": [ {"object_type":"node_groups",    
                      "action":"edit_rules",    
                      "instance":"*"}, ...],    
  "user_ids": [ "1cadd0e0-5887-11e4-8ed6-0800200c9a66", "5clab4b0-588b-11e4-8ed6-0800200c9a66" ],    
  "group_ids": [ "2ca57e30-5887-11e4-8ed6-0800200c9a66" ],    
  "display_name": "A role",    
  "description": "Edit node group rules" }, ...]
```

**GET /roles/<rid>**

Fetched a single role by its ID (rid). Authentication is required.

**Response format**

Returns a 200 OK response with the role object with a full list of permissions and user and group IDs.

For example:

```json
{ "id": 123,    
  "permissions": [ {"object_type":"node_groups",    
                      "action":"edit_rules",    
                      "instance":"*"}, ...],    
  "user_ids": [ "1cadd0e0-5887-11e4-8ed6-0800200c9a66", "5clab4b0-588b-11e4-8ed6-0800200c9a66" ],    
  "group_ids": [ "2ca57e30-5887-11e4-8ed6-0800200c9a66" ],    
  "display_name": "A role",    
  "description": "Edit node group rules" }
```
POST /roles
Creates a role, and attaches to it the specified permissions and the specified users and groups. Authentication is required.

Request format
Accepts a new role object. Any of the arrays can be empty and "description" can be null.

For example:

```
{"permissions": [{"object_type":"node_groups",
                  "action":"edit_rules",
                  "instance":"*"}, ...],
    "user_ids": [
        "1cadd0e0-5887-11e4-8ed6-0800200c9a66",
        "5c1ab4b0-588b-11e4-8ed6-0800200c9a66"],
    "group_ids": [
        "2ca57e30-5887-11e4-8ed6-0800200c9a66"],
    "display_name": "A role",
    "description": "Edit node group rules"}
```

Response format
Returns a 201 Created response with a location header pointing to the new resource.

Error responses
Returns a 409 Conflict response if the role has a name that collides with an existing role.

PUT /roles/<rid>
Replaces a role at the specified ID (rid) with a new role object. Authentication is required.

Request format
Accepts the modified role object.

For example:

```
{"id": 123,
 "permissions": [{"object_type":"node_groups",
                  "action":"edit_rules",
                  "instance":"*"}, ...],
    "user_ids": [
        "1cadd0e0-5887-11e4-8ed6-0800200c9a66",
        "5c1ab4b0-588b-11e4-8ed6-0800200c9a66"],
    "group_ids": [
        "2ca57e30-5887-11e4-8ed6-0800200c9a66"],
    "display_name": "A role",
    "description": "Edit node group rules"}
```

Response format
Returns a 200 OK response with the modified role object.

Error responses
Returns a 409 Conflict response if the new role has a name that collides with an existing role.
DELETE /roles/<rid>
Deletes the role identified by the role ID (rid). Users with this role immediately lose the role and all permissions granted by it, but their session is otherwise unaffected. Access to the next request that the user makes is determined by the new set of permissions the user has without this role.

Response format
Returns a 200 OK response if the role identified by <rid> has been deleted.

Error responses
Returns a 404 Not Found response if no role exists for <rid>.
Returns a 403 Forbidden response if the current user lacks permission to delete the role identified by <rid>.

Permissions endpoints
You assign permissions to user roles to manage user access to objects. The permissions endpoints enable you to get information about available objects and the permissions that can be constructed for those objects.

Permissions keys
The following keys are used with the RBAC v1 API’s permissions endpoints. The available values for these keys are available from the /types endpoint (see below).

<table>
<thead>
<tr>
<th>Key</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_type</td>
<td>A string identifying the type of object this permission applies to.</td>
<td>&quot;node_groups&quot;</td>
</tr>
<tr>
<td>action</td>
<td>A string indicating the type of action this permission permits.</td>
<td>&quot;modify_children&quot;</td>
</tr>
</tbody>
</table>
| instance     | A string containing the primary ID of the object instance this permission applies to, or "*" indicating that it applies to all instances. If the given action does not allow instance specification, "*" should always be used. | "cec7e830-555b-11e4-916c-0800200c9a66" or "*"

GET /types
Lists the objects that integrate with RBAC and demonstrates the permissions that can be constructed by picking the appropriate object_type, action, and instance triple. Authentication is required.

The has_instances flag indicates that the action permission is instance-specific if true, or false if this action permission does not require instance specification.

Response format
Returns a 200 OK response with a listing of types.

For example:

```json
[{  "object_type": "node_groups",  "display_name": "Node Groups",  "description": "Groups that nodes can be assigned to."
  "actions": [{  "name": "view",  "display_name": "View",  "description": "View the node groups",  "has_instances": true
  },{  "name": "modify",
```
Error responses
Returns a 401 Unauthorized response if no user is logged in.
Returns a 403 Forbidden response if the current user lacks permissions to view the types.

POST /permitted
Checks an array of permissions for the subject identified by the submitted identifier.

Request format
This endpoint takes a "token" in the form of a user or a user group's UUID and a list of permissions. This returns true or false for each permission queried, representing whether the subject is permitted to take the given action.

The full evaluation of permissions is taken into account, including inherited roles and matching general permissions against more specific queries. For example, a query for users:edit:1 returns true if the subject has users:edit:1 or users:edit:*.

In the following example, the first permission is querying whether the subject specified by the token is permitted to perform the edit_rules action on the instance of node_groups identified by the ID 4. Note that in reality, node groups and users use UUIDs as their IDs.

```json
{"token": "<subject uuid>",
"permissions": [{
"object_type": "node_groups",
"action": "edit_rules",
"instance": "4"},
{"object_type": "users",
"action": "disable",
"instance": "1"}]
}
```

Response format
Returns a 200 OK response with an array of Boolean values representing whether each submitted action on a specific object type and instance is permitted for the subject. The array always has the same length as the submitted array and each returned Boolean value corresponds to the submitted permission query at the same index.

The example response below was returned from the example request in the previous section. This return means the subject is permitted node_groups:edit_rules:4 but not permitted users:disable:1.

```
[true, false]
```

GET /permitted/<object-type>/<action>
Return an array of permitted instances for the given object-type/action pair based on the current user authentication context.

This endpoint returns the instance values as an array for the given object-type and action pair. If the user does not have permissions for any instance, an empty array will be returned.

If the object-type does not map to a known object-type, the endpoint will return a 404.
If the action does not exist for the given object-type, the endpoint will return a 404.
Example
GET /permitted/node_groups/view
["00000000-0000-4000-8000-000000000000"]

Returns a 200 OK response with a listing of instances.

GET /permitted/<object-type>/<action>/<uuid>
Return an array of permitted instances for the given object-type/action pair based on the user matching the supplied uuid.

This endpoint returns the instance values as an array for the given object-type and action pair. If the user does not have permissions for any instances, an empty array will be returned.

If the object-type does not map to a known object-type, the endpoint will return a 404.
If the action does not exist for the given object-type, the endpoint will return a 404.
If the uuid does not map to a known user, the endpoint will return a 404.

Example
GET /permitted/node_groups/view/fe62d770-5886-11e4-8ed6-0800200c9a66
["00000000-0000-4000-8000-000000000000"]

Returns a 200 OK response with a listing of instances.

Token endpoints
A user's access to PE services can be controlled using authentication tokens. Users can generate their own authentication tokens using the token endpoint.

Related information
Token-based authentication on page 208
Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

Token keys
The following keys are used with the token endpoint.

<table>
<thead>
<tr>
<th>Key</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>login</td>
<td>The user's login for the PE console (required).</td>
</tr>
<tr>
<td>password</td>
<td>The user's password for the PE console (required).</td>
</tr>
<tr>
<td>lifetime</td>
<td>The length of time the token is active before expiration (optional).</td>
</tr>
<tr>
<td>description</td>
<td>Additional metadata about the requested token (optional).</td>
</tr>
<tr>
<td>client</td>
<td>Additional metadata about the client making the token request (optional).</td>
</tr>
<tr>
<td>label</td>
<td>A user-defined label for the token (optional).</td>
</tr>
</tbody>
</table>

The lifetime key
When setting a token's lifetime, specify a numeric value followed by y (years), d (days), h (hours), m (minutes), or s (seconds). For example, a value of 12h is 12 hours. Do not add a space between the numeric value and the unit of

© 2020 Puppet, Inc.
measurement. If you do not specify a unit, it is assumed to be seconds. If you do not want the token to expire, set the lifetime to 0. Setting it to zero gives the token a lifetime of approximately 10 years.

**Tip:** The default lifetime for all tokens is also configurable. See Change the token's default lifetime for configuration instructions.

### The label key
You can choose to select a label for the token that can be used with other RBAC token endpoints. Labels:
- Must be no longer than 200 characters.
- Must not contain commas.
- Must contain something other than whitespace. (Whitespace is trimmed from the beginning and end of the label, though it is allowed elsewhere.)
- Must not be the same as a label for another token for the same user.

Token labels are assigned on a per-user basis: two users can each have a token labelled `my token`, but a single user cannot have two tokens both labelled `my token`. You cannot use labels to refer to other users' tokens.

**POST /auth/token**
Generates an access token for the user whose login information is POSTed. This token can then be used to authenticate requests to PE services using either the `X-Authentication` header or the `token` query parameter.

This route is intended to require zero authentication. While HTTPS is still required (unless PE is explicitly configured to permit HTTP), neither a whitelisted cert nor a session cookie is needed to POST to this endpoint.

### Request format
Accepts a JSON object or curl command with the user's login and password information. The token's lifetime, a user-specified label, and additional metadata can be added, but are not required.

An example JSON request:

```json
{"login": "jeanjackson@example.com",
 "password": "1234",
 "lifetime": "4m",
 "label": "personal workstation token"}
```

An example curl command request:

**Bash**

```bash
type_header='Content-Type: application/json'
cacert="$(puppet config print cacert)"
uri="https://$(puppet config print server):4433/rbac-api/v1/auth/token"
data='{"login": "<USER>",
 "password": "<PASSWORD>",
 "lifetime": "4h",
 "label": "four-hour token"}'
curl --header "$type_header" -cacert "$cacert" --request POST "$uri" --data "$data"
```

The various parts of this curl command request are explained as follows:
- `--header 'Content-Type: application/json'`: sets the `Content-Type` header to `application/json`, which indicates to RBAC that the data being sent is in JSON format.
- `--cacert [FILE]`: Specifies a CA certificate as described in Forming requests for the node classifier. Alternatively, you could use the `--insecure` flag to turn off SSL verification of the RBAC server so that you...
can use the HTTPS protocol without providing a CA cert. If you do not provide one of these options in your curl request, curl complains about not being able to verify the RBAC server.

**Note:** The `--insecure` flag is shown as an example only. You should use your own discretion when choosing the appropriate server verification method for the tool that you are using.

- `--request POST`: This is an HTTP POST request to provide your login information to the RBAC service.
- `https://<HOSTNAME>:<PORT>/rbac-api/v1/auth/token`: Sends the request to the token endpoint. For `HOSTNAME`, provide the FQDN of the server that is hosting the PE console service. If you are making the call from the console server, you can use "localhost." For `PORT`, provide the port that the PE services (node classifier service, RBAC service, and activity service) listen on. The default port is 4433.
- `--data '{"login": "<USER>", "password": "<PASSWORD>", "lifetime": "4h", "label": "four-hour token"}': Provide the user name and password that you use to log in to the PE console. Optionally, set the token’s lifetime and label.

**Response format**

Returns a 200 OK response if the credentials are good and the user is not revoked, along with a token.

For example:

```
{"token": "asd0u0=2jdijasodj-w0duwdhjashd,kjsahdasoi0d9hw0hduashd0a9wdy0whdkaudhaksdhc9chakdh92..."}
```

**Error responses**

Returns a 401 Unauthenticated response if the credentials are bad or the user is revoked.

Returns a 400 Malformed response if something is wrong with the request body.

**Directory service endpoints**

Use the `ds` (directory service) API endpoints to get information about the directory service, test your directory service connection, and replace directory service connection settings.

To connect to the directory service anonymously, specify `null` for the lookup user and lookup password or leave these fields blank.

**Related information**

[External directory settings on page 202](#)

The table below provides examples of the settings used to connect to an Active Directory service and an OpenLDAP service to PE. Each setting is explained in more detail below the table.

**GET /ds**

Get the connected directory service information. Authentication is required.

**Return format**

Returns a 200 OK response with an object representing the connection.

For example:

```
{"display_name": "AD", "hostname": "ds.foobar.com", "port": 10379, ...}
```

If the connection settings have not been specified, returns a 200 OK response with an empty JSON object.

For example:

```
{ }
```
GET /ds/test
Runs a connection test for the connected directory service. Authentication is required.

Return format
If the connection test is successful, returns a 200 OK response with information about the test run.

For example:

```json
{"elapsed": 10}
```

Error responses
- 400 Bad Request if the request is malformed.
- 401 Unauthorized if no user is logged in.
- 403 Forbidden if the current user lacks the permissions to test the directory settings.

```json
{"elapsed": 20, "error": "..."}
```

PUT /ds/test
Performs a connection test with the submitted settings. Authentication is required.

Request format
Accepts the full set of directory settings keys with values defined.

Return format
If the connection test is successful, returns information about the test run.

For example:

```json
{"elapsed": 10}
```

Error responses
If the request times out or encounters an error, returns information about the test run.

For example:

```json
{"elapsed": 20, "error": "..."}
```

PUT /ds
Replaces current directory service connection settings. Authentication is required.

When changing directory service settings, you must specify all of the required directory service settings in the PUT request, including the required settings that are remaining the same. You do not need to specify optional settings unless you are changing them.

Request format
Accepts directory service connection settings. To "disconnect" the DS, PUT either an empty object ("{}") or the settings structure with all values set to null.

For example:

```json
{"hostname": "ds.somehost.com",
"name",
"port": 10389,
```
"login": "frances", ...}

**Working with nested groups**

When authorizing users, the RBAC service has the ability to search nested groups. Nested groups are groups that are members of external directory groups. For example, if your external directory has a "System Administrators" group, and you've given that group the "Superusers" user role in RBAC, then RBAC also searches any groups that are members of the "System Administrators" group and assign the "Superusers" role to users in those member groups.

By default, RBAC does not search nested groups. To enable nested group searches, specify the `search_nested_groups` field and give it a value of `true`.

**Note:** In PE 2015.3 and earlier versions, RBAC's default was to search nested groups. When **upgrading** from one of these earlier versions, this default setting is preserved and RBAC continues to search nested groups. If you have a large number of nested groups, you might experience a slowdown in performance when users are logging in because RBAC is searching the entire hierarchy of groups. To avoid performance issues, change the `search_nested_groups` field to `false` for a more shallow search in which RBAC searches only the groups it has been configured to use for user roles.

**Using StartTLS connections**

To use a StartTLS connection, specify "`start_tls`: true". When set to `true`, StartTLS is used to secure your connection to the directory service, and any certificates that you have configured through the DS trust chain setting is used to verify the identity of the directory service. When specifying StartTLS, make sure that you don't also have SSL set to `true`.

**Disabling matching rule in chain**

When PE detects an Active Directory that supports the LDAP_MATCHING_RULE_IN_CHAIN feature, it automatically uses it. Under some specific circumstances, you might need to disable this setting. To disable it, specify "`disable_ldap_matching_rule_in_chain`: true" in the PUT request. This is an optional setting.

**Return format**

Returns a 200 OK response with an object showing the updated connection settings.

For example:

```json
{
    "hostname": "ds.somehost.com",
    "port": 10389,
    "login": "frances", ...
}
```

**Password endpoints**

When local users forget passwords or lock themselves out of PE by attempting to log in with incorrect credentials too many times, you must generate a password reset token for them. The password endpoints enable you to generate password reset tokens for a specific local user or with a token that contains a temporary password in the body.

**Tip:** The PE console admin password can also be reset using a password reset script available on the PE console node.

**Tip:** 10 is the default number of login attempts that can be made with incorrect credentials before a user is locked out. You can change the value by configuring the `failed-attempts-lockout` parameter.

**Related information**

[Reset the console administrator password](https://docs.puppet.com/pe/193/html/#reset-the-console-administrator-password) on page 193
To reset the administrator password for console access, use the `puppet infrastructure` command.

**POST /users/:sid/password/reset**

Generates a single-use password reset token for the specified local user.

The generated token can be used to reset the password only one time and it has a limited lifetime. The lifetime is based on a configuration value `puppet_enterprise::profile::console::rbac_password_reset_expiration` (number of hours). The default value is 24 hours. Authentication is required.

This token is to be given to the appropriate user for use with the `/auth/reset` endpoint.

**Response format**

Returns a 201 Created response. For example:

```json
eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCJ9.eyJpc3MiOiJhcGlfdXNlciIsInN1YiI6ImE3YzA4MTY3LWE1MDUtNDBlMy05NWQxLWQzMTE4NDQwM2Q5ZiIsImV4cCI6MTU0ODg4NTU0OCwiaWF0IjoxNTQ4Nzk5MTQ4fQ.qOG0w5UuZiBrT8yPoTG3YHwOhhkchrUh7kvFNiBFw0gPyfyZ2yhfjHcffJ-p0aUcdmBtuD95j9NGEAPtTwsDcux0_33hpz03m0Rp3hDSjb1QwyTBTuf2rpqyamaYo1VRw-Ecu606U1qBAqkQ9rMtocRT06YTQ8M6p9RxIF_k_u5YjZDrhLSqYxg-LY-cY2IFow_XFPw9vWBuDX1lLB9TqJoI2NVBYmoHABzoKrn-V-dKGRAW-P-GBTwdtvS-oD5f1kbDBkWangGq2jb2Ghszhb8jdK9wWQ_8fnOcUK_kLlbE7Wrh0htK045tT9BPazwZaZWagHiojI_YFyJfBiB_REM3xquRE-4C2EbeQld_u-WZGnJp2V_HgK4Spd56V-anuDq1aakaW31zDJKJuFI4CxUE8_xpfFLLRdofTHrLPwo5dszbKK-9xw3JfIMhnsK4e2H_5Nywkw0951vonKuYp
```

**Error responses**

Returns a 403 Forbidden response if the user does not have permissions to create a reset path for the specified user, or if the user is a remote user.

Returns a 404 Not Found response if a user with the given identifier does not exist.

**POST /auth/reset**

Resets a local user's password using a one-time token obtained via the `/users/:sid/password/reset` endpoint, with the new password in the body. No authentication is required to use this endpoint.

**Request format**

The appropriate user is identified in the payload of the token. This endpoint does not establish a valid logged-in session for the user.

For example:

```json
{"token": "text of token goes here", "password": "someotherpassword"}
```

**Response format**

Returns a 200 OK response if the token is valid and the password has been successfully changed.

**Error responses**

Returns a 403 Permission Denied response if the token has already been used or is invalid.

**PUT /users/current/password**

Changes the password for the current local user. A payload containing the current password must be provided. Authentication is required.

**Request format**

The current and new passwords must both be included.
For example:

```json
{"current_password": "somepassword",
 "password": "someotherpassword"}
```

**Response format**

Returns a 200 OK response if the password has been successfully changed.

**Error responses**

Returns a 403 Forbidden response if the user is a remote user, or if `current_password` doesn't match the current password stored for the user. The body of the response includes a message that specifies the cause of the failure.

**RBAC service errors**

You’re likely to encounter some errors when using the RBAC API. You’ll want to familiarize yourself with the error response descriptions and the general error responses.

**Error response format**

When the client specifies an `accept` header in the request with type `application/json`, the RBAC service returns errors in a standard format.

Each response is an object containing the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>A string classifying the error. It should be the same for all errors that have the same type of information in their <code>details</code> key.</td>
</tr>
<tr>
<td>msg</td>
<td>A human-readable message describing the error.</td>
</tr>
<tr>
<td>details</td>
<td>Additional machine-readable information about the error condition. The format of this key's value varies between kinds of errors, but is the same for each kind of error.</td>
</tr>
</tbody>
</table>

When returning errors in `text/html`, the body is the contents of the `msg` field.

**General error responses**

Any endpoint accepting a JSON body can return several kinds of 400 Bad Request responses.

<table>
<thead>
<tr>
<th>Response</th>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>malformed-request</td>
<td>400</td>
<td>The submitted data is not valid JSON. The <code>details</code> key consists of one field, <code>error</code>, which contains the error message from the JSON parser.</td>
</tr>
<tr>
<td>Response</td>
<td>Status</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>schema-violation</td>
<td>400</td>
<td>The submitted data has an unexpected structure, such as invalid fields or missing required fields. The <code>msg</code> contains a description of the problem. The <code>details</code> are an object with three keys:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>submitted</code>: The submitted data as it was seen during schema validation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>schema</code>: The expected structure of the data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>error</code>: A structured description of the error.</td>
</tr>
<tr>
<td>inconsistent-id</td>
<td>400</td>
<td>Data was submitted to an endpoint where the ID of the object is a part of the URL and the submitted data contains an <code>id</code> field with a different value. The <code>details</code> key consists of two fields, <code>url-id</code> and <code>body-id</code>, showing the IDs from both sources.</td>
</tr>
<tr>
<td>invalid-id-filter</td>
<td>400</td>
<td>A URL contains a filter on the ID with an invalid format. No details are given with this error.</td>
</tr>
<tr>
<td>invalid-uuid</td>
<td>400</td>
<td>An invalid UUID was submitted. No details are given with this error.</td>
</tr>
<tr>
<td>user-unauthenticated</td>
<td>401</td>
<td>An unauthenticated user attempted to access a route that requires authentication.</td>
</tr>
<tr>
<td>user-revoked</td>
<td>401</td>
<td>A user who has been revoked attempted to access a route that requires authentication.</td>
</tr>
<tr>
<td>api-user-login</td>
<td>401</td>
<td>A person attempted to log in as the api_user with a password (api_user does not support username/password authentication).</td>
</tr>
<tr>
<td>remote-user-conflict</td>
<td>401</td>
<td>A remote user who is not yet known to RBAC attempted to authenticate, but a local user with that login already exists.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The solution is to change either the local user's login in RBAC, or to change the remote user's login, either by changing the <code>user_lookup_attr</code> in the DS settings or by changing the value in the directory service itself.</td>
</tr>
<tr>
<td>permission-denied</td>
<td>403</td>
<td>A user attempted an action that they are not permitted to perform.</td>
</tr>
<tr>
<td>Response</td>
<td>Status</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>admin-user-immutable</td>
<td>403</td>
<td>A user attempted to edit metadata or associations belonging to the default roles (“Administrators”, “Operators”, “Code Deployers”, or “Viewers”) or default users (“admin” or “api_user”) that they are not allowed to change.</td>
</tr>
<tr>
<td>admin-user-not-in-admin-role</td>
<td></td>
<td></td>
</tr>
<tr>
<td>default-roles-immutable</td>
<td></td>
<td></td>
</tr>
<tr>
<td>conflict</td>
<td>409</td>
<td>A value for a field that is supposed to be unique was submitted to the service and another object has that value. For example, when a user is created with the same login as an existing user.</td>
</tr>
<tr>
<td>invalid-associated-id</td>
<td>422</td>
<td>An object was submitted with a list of associated IDs (for example, user_ids) and one or more of those IDs does not correspond to an object of the correct type.</td>
</tr>
<tr>
<td>no-such-user-LDAP</td>
<td>422</td>
<td>An object was submitted with a list of associated IDs (for example, user_ids) and one or more of those IDs does not correspond to an object of the correct type.</td>
</tr>
<tr>
<td>no-such-group-LDAP</td>
<td></td>
<td></td>
</tr>
<tr>
<td>non-unique-lookup-attr</td>
<td>422</td>
<td>A login was attempted but multiple users are found via LDAP for the given username. The directory service settings must use a user_lookup_attr that is guaranteed to be unique within the provided user's RDN.</td>
</tr>
<tr>
<td>server-error</td>
<td>500</td>
<td>Occurs when the server throws an unspecified exception. A message and stack trace should be available in the logs.</td>
</tr>
</tbody>
</table>

**Configuration options**

There are various configuration options for the RBAC service. Each section can exist in its own file or in separate files.

**RBAC service configuration**

You can configure the RBAC service's settings to specify the duration before inactive user accounts expire, adjust the length of user sessions, the number of times a user can attempt to log in, and the length of time a password reset token is valid. You can also define a whitelist of certificates.

These configuration parameters are not required, but when present must be under the `rbac` section, as in the following example:

```yaml
rbac: {
  # Duration in days before an inactive account expires
  account-expiry-days: 1
  # Duration in minutes that idle user accounts are checked
  account-expiry-check-minutes: 60
  # Duration in hours that a password reset token is viable
  password-reset-expiration: 24
}
```

© 2020 Puppet, Inc.
# Duration in minutes that a session is viable

```
session-timeout: 60
failed-attempts-lockout: 10
```

**account-expiry-days**

This parameter is a positive integer that specifies the duration, in days, before an inactive user account expires. The default value is undefined. To activate this feature, add a value of 1 or greater.

If a non-superuser hasn't logged into the console during this specified period, their user status updates to revoked.

After creating an account, if a non-superuser hasn't logged in to the console during the specified period, their user status updates to revoked.

**Important:** If the `account-expiry-days` parameter is not specified, or has a value of less than 1, the `account-expiry-check-minutes` parameter is ignored.

**account-expiry-check-minutes**

This parameter is a positive integer that specifies how often, in minutes, the application checks for idle user accounts. The default value is 60 minutes.

**password-reset-expiration**

When a user doesn't remember their current password, an administrator can generate a token for them to change their password. The duration, in hours, that this generated token is valid can be changed with the `password-reset-expiration` config parameter. The default value is 24.

**session-timeout**

This parameter is a positive integer that specifies how long a user's session should last, in minutes. This session is the same across node classifier, RBAC, and the console. The default value is 60.

**failed-attempts-lockout**

This parameter is a positive integer that specifies how many failed login attempts are allowed on an account before that account is revoked. The default value is 10.

**Note:** If you change this value, create a new file or Puppet resets back to 10 when it next runs. Create the file in an RBAC section of `/etc/puppetlabs/console-services/conf.d`.

**certificate-whitelist**

This parameter is a path for specifying the file that contains the names of hosts that are allowed to use RBAC APIs and other downstream component APIs, such as the Node Classifier and the Activity services. This configuration is for the users who want to script interaction with the RBAC service.

Users must connect to the RBAC service with a client certificate that has been specified in this `certificate-whitelist` file. A successful match of the client certificate and this certificate-whitelist allows access to the RBAC APIs as the api_user. By default, this user is an administrator and has all available permissions.

The certificate whitelist contains, at minimum, the certificate for the nodes PE is installed on.

**RBAC database configuration**

Credential information for the RBAC service is stored in a PostgreSQL database.

The configuration information for that database is found in the 'rbac-database' section of the config.

For example:

```
rbac-database: {
```
```
  classname: org.postgresql.Driver
  subprotocol: postgresql
  subname: "//<path-to-host>:5432/perbac"
  user: <username here>
  password: <password here>
```

**classname**

Used by the RBAC service for connecting to the database; this option should always be `org.postgresql.Driver`.

**subprotocol**

Used by the RBAC service for connecting to the database; this option should always be `postgresql`.

**subname**

JDBC connection path used by the RBAC service for connecting to the database. This should be set to the hostname and configured port of the PostgreSQL database. `perbac` is the database the RBAC service uses to store credentials.

**user**

This is the username the RBAC service should use to connect to the PostgreSQL database.

**password**

This is the password the RBAC service should use to connect to the PostgreSQL database.

---

**RBAC API v2**

The role-based access control (RBAC) service enables you to manage users, directory groups, and roles.

- **Tokens endpoints** on page 238
  
  A user’s access to PE services can be controlled using authentication tokens. Users can revoke authentication tokens using the `tokens` endpoints.

**Related information**

- **API index** on page 33
  
  APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

**Tokens endpoints**

A user’s access to PE services can be controlled using authentication tokens. Users can revoke authentication tokens using the `tokens` endpoints.

**Related information**

- **Token-based authentication** on page 208
Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

**DELETE /tokens**

Use this endpoint to revoke one or more authentication tokens, ensuring the tokens can no longer be used with RBAC.

### Parameters

The tokens must be specified using at least one of the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>revoke_tokens</td>
<td>A list of complete authentication tokens to be revoked.</td>
</tr>
<tr>
<td>revoke_tokens_by_usernames</td>
<td>A list of usernames whose tokens are to be revoked.</td>
</tr>
<tr>
<td>revoke_tokens_by_labels</td>
<td>A list of the labels of tokens to revoke (only tokens owned by the user making the request can be revoked in this manner).</td>
</tr>
</tbody>
</table>

You can supply parameters either as query parameters or as JSON-encoded in the body. If you include them as query parameters, separate the tokens, labels, or usernames by commas:

```
/tokens?revoke_tokens_by_usernames=<USER_NAME>,<USER_NAME>
```

If you encoded them in the body, supply them as a JSON array:

```
{"revoke_tokens_by_usernames": ["<USER NAME>", "<USER NAME>"]}
```

If you provide a parameter as both a query parameter and in the JSON body, the values from the two sources are combined. It is not an error to specify the same token using multiple means (such as by providing the entire token to the `revoke_tokens` parameter and also including its label in the value of `revoke_tokens_by_labels`).

In the case of an error, malformed or otherwise input, or bad request data, the endpoint still attempts to revoke as many tokens as possible. This means it's possible to encounter multiple error conditions in a single request, such as if there were malformed usernames supplied in the request and a database error occurred when trying to revoke the well-formed usernames.

All operations on this endpoint are idempotent—it is not an error to revoke the same token two or more times.

Any user can revoke any token by supplying the complete token in the `revoke_tokens` query parameter or request body field.

To revoke tokens by username, the user making the request must have the "Users Revoke" permission for that user.

### Example JSON body

The following is an example JSON body using each of the available parameters.

```
{"revoke_tokens": ["eyJhbGciOiJSUzUxUmMiIsInR5cCI6IkpXVCJ9.eyJpc3MiOiJhZG1pbiIsImlhdCI6MTQzOTQ5Mzg0NiwiZXhwIjoxNDM5NDk0MTQ2LCJzdWIiOnsibG9naW4iOiJhZG1pbiIsImlkIjoiNDJiZjM1MWMtZjllYy00MGFmLTg0YWQtZTk3NmZlYzdmNGJkIn19.gCXZVMJ1TwRKMKCV3OESK-

rOBTLeu1a6assH-ggpHgVKTFOomEXM6UTjp1NpuP01rNz9JM1xWhl8WpExH11__136D1N3m32kw-oV6GzXR70xg_N2CiWObw-x155aUUC4KkyPtDmNvnc1n4"]
"revoke_tokens_by_labels": ["Workstation Token", "VPS Token"],
"revoke_tokens_by_usernames": ["<USER NAME>", "<USER NAME>"],
```

© 2020 Puppet, Inc.
Response codes

The server uses the following response codes:

<table>
<thead>
<tr>
<th>Code</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>No Content</td>
</tr>
<tr>
<td>500</td>
<td>Application Error</td>
</tr>
<tr>
<td>403</td>
<td>Sent if the user lacks the permission to revoke one of the supplied usernames and no database error occurred.</td>
</tr>
<tr>
<td>400</td>
<td>Malformed</td>
</tr>
</tbody>
</table>

All error responses follow the standard JSON error format, meaning they have kind, msg, and details keys.

The kind key is puppetlabs.rbac/database-token-error if the response is a 500, permission-denied if the response is a 403, and malformed-token-request if the response is a 400.

The msg key contains an English-language description of the problems encountered while processing the request and performing the revocations, ending with either "No tokens were revoked" or "All other tokens were successfully revoked", depending on whether any operations were successful.

The details key contains an object with arrays in the malformed_tokens, malformed_usernames, malformed_labels, nonexistent_usernames, permission_denied_usernames, and unrecognized_parameters fields, as well as the Boolean field other_tokens_revoked.

The arrays all contain bad input from the request, and the other_tokens_revoked field's value indicates whether any of the revocations specified in the request were successful or not.

Example error body

The server returns an error body resembling the following:

```json
{"kind": "malformed-request",
 "msg": "The following user does not exist: FormerEmployee. All other tokens were successfully revoked.",
 "details": {"malformed_tokens": [],
 "malformed_labels": [],
 "malformed_usernames": [],
 "nonexistent_usernames": ["FormerEmployee"],
 "permission_denied_usernames": [],
 "unrecognized_parameters": [],
 "other_tokens_revoked": true}}
```
DELETE /tokens/<token>
Use this endpoint to revoke a single token, ensuring that it can no longer be used with RBAC. Authentication is required.

This endpoint is equivalent to DELETE /tokens?revoke_tokens={TOKEN}.
This API can be used only by the admin or API user.

Response codes
The server uses the following response codes:

<table>
<thead>
<tr>
<th>Code</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>204 No Content</td>
<td>Sent if all operations are successful.</td>
</tr>
<tr>
<td>400 Malformed</td>
<td>Sent if the token is malformed.</td>
</tr>
</tbody>
</table>

The error response is identical to DELETE /tokens.

Example error body
The error response from this endpoint is identical to DELETE /tokens.

```json
{"kind": "malformed-request", "msg": "The following token is malformed: notAToken. This can be caused by an error while copying and pasting. No tokens were revoked."
"details": {"malformed_tokens": ["notAToken"],
"malformed_labels": [],
"malformed_usernames": [],
"nonexistent_usernames": [],
"permission_denied_usernames": [],
"unrecognized_parameters": [],
"other_tokens_revoked": false}}
```

POST /auth/token/authenticate
Use this endpoint to exchange a token for a map representing an RBAC subject and associated token data. This endpoint does not require authentication.

This endpoint accepts a JSON body containing entries for token and update_last_activity?. The token field is a string containing an authentication token. The update_last_activity? field is a Boolean data type that indicates whether a successful authentication should update the last_active timestamp for the token.

Response codes
The server uses the following response codes:

<table>
<thead>
<tr>
<th>Code</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 OK</td>
<td>The subject represented by the token.</td>
</tr>
<tr>
<td>400 invalid-token</td>
<td>The provided token was either tampered with or could not be parsed.</td>
</tr>
<tr>
<td>403 token-revoked</td>
<td>The provided token has been revoked.</td>
</tr>
<tr>
<td>403 token-expired</td>
<td>The token has expired and is no longer valid.</td>
</tr>
<tr>
<td>403 token-timed-out</td>
<td>The token has timed out due to inactivity.</td>
</tr>
</tbody>
</table>
Example JSON body

```json
{
    "token": "0VZZ6geJQK8zJGKxBdqlatTsMLAsfCQFJuRwxsmNgCr4",
    "update_last_activity": false
}
```

Example return

```json
{
    "description": null,
    "creation": "YYYY-MM-DDT22:24:30Z",
    "email": "franz@kafka.com",
    "is_revoked": false,
    "last_active": "YYYY-MM-DDT22:24:31Z",
    "expiration": "YYYY-MM-DDT22:29:30Z",
    "is_remote": false,
    "client": null,
    "login": "franz@kafka.com",
    "is_superuser": false,
    "label": null,
    "id": "c84bae61-f668-4a18-9a4a-5e33a97b716c",
    "role_ids": [1, 2, 3],
    "user_id": "c84bae61-f668-4a18-9a4a-5e33a97b716c",
    "timeout": null,
    "display_name": "Franz Kafka",
    "is_group": false
}
```

Activity service API

The activity service logs changes to role-based access control (RBAC) entities, such as users, directory groups, and user roles.

- **Forming activity service API requests** on page 242
  Token-based authentication is required to access the activity service API. You can authenticate requests with user authentication tokens or whitelisted certificates.
- **Event types reported by the activity service** on page 243
  Activity reporting provides a useful audit trail for actions that change role-based access control (RBAC) entities, such as users, directory groups, and user roles.
- **Events endpoints** on page 246
  Use the events endpoints to retrieve activity service events.

Related information

**API index** on page 33
APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

**Forming activity service API requests**
Token-based authentication is required to access the activity service API. You can authenticate requests with user authentication tokens or whitelisted certificates.

By default, the activity service listens on port 4433. All endpoints are relative to the /activity-api/ path. So, for example, the full URL for the /v1/events endpoint on localhost is https://localhost:4433/activity-api/v1/events.
Authentication using tokens

Insert a user authentication token variable in an activity service API request.

1. Generate a token: puppet-access login
2. Use puppet-access show to populate an authentication header, and use that header in your API request.

Bash

```bash
puppet-access login

auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/activity-api/v1/events?
   service_id=classifier"

curl --insecure --header "$auth_header" "$uri"
```

Authentication using whitelisted certificate

You can also authenticate requests using a certificate listed in RBAC's certificate whitelist, located at /etc/puppetlabs/console-services/rbac-certificate-whitelist. Note that if you edit this file, you must reload the pe-console-services service (run sudo service pe-console-services reload) for your changes to take effect.

Attach the certificate using the command line, as demonstrated in the example curl query below. You must have the whitelisted certificate name (which must match a name in the /etc/puppetlabs/console-services/rbac-certificate-whitelist file) and the private key to run the script.

Bash

```bash
type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/activity-api/v1/events?
   service_id=classifier"

curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key"
   "$uri"
```

You do not need to use an agent certificate for authentication. You can use puppet cert generate to create a new certificate specifically for use with the API.

Related information

Token-based authentication on page 208

Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

Event types reported by the activity service

Activity reporting provides a useful audit trail for actions that change role-based access control (RBAC) entities, such as users, directory groups, and user roles.

Local users

These events are displayed in the console on the Activity tab for the affected user.
### Event Management

<table>
<thead>
<tr>
<th>Event</th>

<td>Administrator (42bf351c-f9ec-40af-84ad-e976fec7f4bd) revoked an authentication token belonging to Amari Perez (c84bae61-f668-4a18-9a4a-5e33a97b716c), issued at 2016-02-17T21:53:23.000Z and expiring at 2016-02-17T21:58:23.000Z.</td>
</tr>
<tr>
<td>Revocation by username</td>
<td>All tokens for a username are revoked. These events are exposed in the console on the Activity tab for the user performing the revocation.</td>
<td>Administrator (42bf351c-f9ec-40af-84ad-e976fec7f4bd) revoked all authentication tokens belonging to Amari Perez (c84bae61-f668-4a18-9a4a-5e33a97b716c).</td>
</tr>
</tbody>
</table>

**Directory service settings**

These events are not exposed in the console. The activity service API must be used to see these events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update settings (except password)</td>
<td>A setting is changed in the directory service settings.</td>
<td>User rdn set to &quot;ou=users&quot;.</td>
</tr>
<tr>
<td>Update directory service password</td>
<td>The directory service password is changed.</td>
<td>Password updated.</td>
</tr>
</tbody>
</table>

**Events endpoints**

Use the events endpoints to retrieve activity service events.

**GET /v1/events**

Fetches activity service events. Web session authentication is required.

**Request format**

The /v1/events endpoint supports filtering through query parameters.

- **service_id**
  - *required* The ID of the service: classifier, code-manager, pe-console, or rbac.

- **subject_type**
  - The subject who performed the activity: users.

- **subject_id**
  - Comma-separated list of IDs associated with the defined subject type.

- **object_type**
  - The object affected by the activity: node, node_groups, users, user_groups, roles, environment, or directory_server_settings.
**object_id**  
Comma-separated list of IDs associated with the defined object type.

**offset**  
Number of commits to skip before returning events.

**limit**  
Maximum number of events to return. Default is 1000 events.

**Examples**

**Bash**

```bash
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/activity-api/v1/events?service_id=classifier&subject_type=users&subject_id=6868e4af-2996-46c6-8e42-1ae873f8a0ba" 
curl --insecure --header "$auth_header" "$uri"

uri="https://$(puppet config print server):4433/activity-api/v1/events?service_id=pe-console&object_type=node&object_id=emerald-1.platform9.example.com"
curl --insecure --header "$auth_header" "$uri"
```

**Response format**

Responses are returned in a structured JSON format. Example return:

```json
{
    "commits": [
        {
            "object": {
                "id": "b55c209d-e68f-4096-9a2c-5ae52dd2500c", "name": "web_servers"
            },
            "subject": {
                "id": "6868e4af-2996-46c6-8e42-1ae873f8a0ba", "name": "kai.evens"
            },
            "timestamp": "2019-03-05T18:52:27Z", "events": [
                {
                    "message": "Deleted the \"web_servers\" group with id b55c209d-e68f-4096-9a2c-5ae52dd2500c"
                }
            ],
            "offset": 0, "limit": 1, "total-rows": 5
        }
    ],
    "offset": 0, "limit": 1, "total-rows": 2915
}
```
GET /v1/events.csv
Fetched activity service events and returns in a flat CSV format. Token-based authentication is required.

Request format
The /v1/events.csv endpoint supports the same parameters as /v1/events

Examples
Bash

```
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/activity-api/v1/events.csv?
service_id=classifier&subject_type=users&subject_id=6868e4af-2996-46c6-8e42-1ae873f8a0ba"

curl --insecure --header "$auth_header" "$uri"
```

Response format
Responses are returned in a flat CSV format. Example return:

```

```
Inspectiong your infrastructure

The Puppet Enterprise console offers a variety of tools you can use to monitor the current state of your infrastructure, see the results of planned or unplanned changes to your Puppet code, and investigate problems. These tools are grouped in the Enforcement section of the console’s sidebar.

- Monitoring infrastructure state on page 249
  When nodes fetch their configurations from the Puppet master, they send back inventory data and a report of their run. This information is summarized on the Status page in the console.

- Viewing and managing packages on page 254
  The Packages page in the console shows all packages in use across your infrastructure by name, version, and provider, as well as the number of instances of each package version in your infrastructure. Use the Packages page to quickly identify which nodes are impacted by packages you know are eligible for maintenance updates, security patches, and license renewals.

- Infrastructure reports on page 256
  Each time Puppet runs on a node, it generates a report that provides information such as when the run took place, any issues encountered during the run, and the activity of resources on the node. These reports are collected on the Reports page in the console.

- Analyzing changes across Puppet runs on page 260
  The Events page in the console shows a summary of activity in your infrastructure. You can analyze the details of important changes, and investigate common causes behind related events. You can also examine specific class, node, and resource events, and find out what caused them to fail, change, or run as no-op.

- Collecting value analytics on page 262
  The value API provides insight into time and money freed by PE automation.

- Viewing and managing Puppet Server metrics on page 266
  Puppet Server can provide performance and status metrics to external services for monitoring server health and performance over time.

- Status API on page 274
  The status API allows you to check the health of PE components and services. It can be useful for automated monitoring of your infrastructure, removing unhealthy service instances from a load-balanced pool, checking configuration values, or troubleshooting issues in PE.

Monitoring infrastructure state

When nodes fetch their configurations from the Puppet master, they send back inventory data and a report of their run. This information is summarized on the Status page in the console.

The Status page displays the most recent run status of each of your nodes so you can quickly find issues and diagnose their causes. You can also use this page to gather essential information about your infrastructure at a glance, such as how many nodes your Puppet master is managing, and whether any nodes are unresponsive.

Node run statuses

The Status page displays the run status of each node following the most recent Puppet run. There are 10 possible run statuses.

Nodes run in enforcement mode

- With failures
  This node’s last Puppet run failed, or Puppet encountered an error that prevented it from making changes.
The error is usually tied to a particular resource (such as a file) managed by Puppet on the node. The node as a whole might still be functioning normally. Alternatively, the problem might be caused by a situation on the Puppet master, preventing the node's agent from verifying whether the node is compliant.

 dificult unanimously tied to a particular resource (such as a file) managed by Puppet on the node. The node as a whole might still be functioning normally. Alternatively, the problem might be caused by a situation on the Puppet master, preventing the node's agent from verifying whether the node is compliant.

**With corrective changes**

During the last Puppet run, Puppet found inconsistencies between the last applied catalog and this node’s configuration, and corrected those inconsistencies to match the catalog.

**Note:** Corrective change reporting is available only on agent nodes running PE 2016.4 and later. Agents running earlier versions report all change events as "with intentional changes."

**With intentional changes**

During the last Puppet run, changes to the catalog were successfully applied to the node.

**Unchanged**

This node's last Puppet run was successful, and it was fully compliant. No changes were necessary.

**Nodes run in no-op mode**

**Note:** No-op mode reporting is available only on agent nodes running PE 2016.4 and later. Agents running earlier versions report all no-op mode runs as "would be unchanged."

**With failures**

This node’s last Puppet run in no-op mode failed, or Puppet encountered an error that prevented it from simulating changes.

**Would have corrective changes**

During the last Puppet run, Puppet found inconsistencies between the last applied catalog and this node’s configuration, and would have corrected those inconsistencies to match the catalog.

**Would have intentional changes**

During the last Puppet run, catalog changes would have been applied to the node.

**Would be unchanged**

This node’s last Puppet run was successful, and the node was fully compliant. No changes would have been necessary.

**Nodes not reporting**

**Unresponsive**

The node hasn't reported to the Puppet master recently. Something might be wrong. The cutoff for considering a node unresponsive defaults to one hour, and can be configured via the puppet-enterprise::console_services::no_longer_reporting_cutoff parameter. See Configure the PE console and console-services on page 158 for more information.

Check the run status table to see the timestamp for the last known Puppet run for the node and an indication of whether its last known run was in no-op mode. Correct the problem to resume Puppet runs on the node.

**Have no reports**

Although Puppet Server is aware of this node's existence, the node has never submitted a Puppet report for one or more of the following reasons: it's a newly commissioned node; it has never come online; or its copy of Puppet is not configured correctly.

**Note:** Expired or deactivated nodes are displayed on the Status page for seven days. To extend the amount of time that you can view or search for these nodes, change the node-ttl setting in PuppetDB. Changing this setting affects resources and exported resources.
Special categories

In addition to reporting the run status of each node, the Status page provides a secondary count of nodes that fall into special categories.

Intended catalog failed

During the last Puppet run, the intended catalog for this node failed, so Puppet substituted a cached catalog, as per your configuration settings.

This typically occurs when you have compilation errors in your Puppet code. Check the Puppet run’s log for details.

This category is shown only if one or more agents fail to retrieve a valid catalog from Puppet Server.

Enforced resources found

During the last Puppet run in no-op mode, one or more resources was enforced, as per your use of the `noop => false` metaparameter setting.

This category is shown only if enforced resources are present on one or more nodes.

How Puppet determines node run statuses

Puppet uses a hierarchical system to determine a single run status for each node. This system gives higher priority to the activity types most likely to cause problems in your deployment, so you can focus on the nodes and events most in need of attention.

During a Puppet run, several activity types might occur on a single node. A node’s run status reflects the activity with the highest alert level, regardless of how many events of each type took place during the run. Failure events receive the highest alert level, and no change events receive the lowest.

<table>
<thead>
<tr>
<th>Run status</th>
<th>Definitely happened</th>
<th>Might also have happened</th>
</tr>
</thead>
<tbody>
<tr>
<td>❗️</td>
<td>Failure</td>
<td>Corrective change, intentional change, no change</td>
</tr>
<tr>
<td>🔄</td>
<td>Corrective change</td>
<td>Intentional change, no change</td>
</tr>
<tr>
<td>⚙️</td>
<td>Intentional change</td>
<td>No change</td>
</tr>
<tr>
<td>✔️</td>
<td>No change</td>
<td></td>
</tr>
</tbody>
</table>

For example, during a Puppet run in enforcement mode, a node with 100 resources receives intentional changes on 30 resources, corrective changes on 10 resources, and no changes on the remaining 60 resources. This node’s run status is “with corrective changes.”

Node run statuses also prioritize run mode (either enforcement or no-op) over the state of individual resources. This means that a node run in no-op mode is always reported in the Nodes run in no-op column, even if some of its resource changes were enforced. Suppose the no-op flags on a node’s resources are all set to false. Changes to the resources are enforced, not simulated. Even so, because it is run in no-op mode, the node’s run status is “would have intentional changes.”

Filtering nodes on the Status page

You can filter the list of nodes displayed on the Status page by run status and by node fact. If you set a run status filter, and also set a node fact filter, the table takes both filters into account, and shows only those nodes matching both filters.

Clicking Remove filter removes all filters currently in effect.

The filters you set are persistent. If you set run status or fact filters on the Status page, they continue to be applied to the table until they're changed or removed, even if you navigate to other pages in the console or log out. The persistent storage is associated with the browser tab, not your user account, and is cleared when you close the tab.

© 2020 Puppet, Inc.
Important: The filter results count and the fact filter matching nodes counts are cached for two minutes after first retrieval. This reduces the total load on PuppetDB and decreases page load time, especially for fact filters with multiple rows. As a result, the displayed counts might be up to two minutes out of date.

Filter by node run status
The status counts section at the top of the Status page shows a summary of the number of nodes with each run status as of the last Puppet run. Filter nodes by run status to quickly focus on nodes with failures or change events.

In the status counts section, select a run status (such as with corrective changes or have no reports) or a run status category (such as Nodes run in no-op).

Filter by node fact
You can create a highly specific list of nodes for further investigation by using the fact filter tool.

For example, you can check that nodes you've updated have successfully changed, or find out the operating systems or IP addresses of a set of failed nodes to better understand the failure. You might also filter by facts to fulfill an auditor's request for information, such as the number of nodes running a particular version of software.

1. Click Filter by fact value. In the Fact field, select one of the available facts. An empty fact field is not allowed.

   Tip: To see the facts and values reported by a node on its most recent run, click the node name in the Run status table, then select the node’s Facts tab.

2. Select an Operator:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>is</td>
<td></td>
</tr>
<tr>
<td>!=</td>
<td>is not</td>
<td></td>
</tr>
<tr>
<td>~</td>
<td>matches a regular expression</td>
<td>Select this operator to use wildcards and other regular expressions if you want to find matching facts without having to specify the exact value.</td>
</tr>
<tr>
<td></td>
<td>(regex)</td>
<td></td>
</tr>
<tr>
<td>!~</td>
<td>does not match a regular expression (regex)</td>
<td></td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
</tbody>
</table>

3. In the Value field, enter a value. Strings are case-sensitive, so make sure you use the correct case.

The filter displays an error if you use an invalid string operator (for example, selecting a numeric value operator such as >= and entering a non-numeric string such as pilsen as the value) or enter an invalid regular expression.

Note: If you enter an invalid or empty value in the Value field, PE takes the following action in order to avoid a filter error:

- Invalid or empty Boolean facts are processed as false, and results are retrieved accordingly.
- Invalid or empty numeric facts are processed as 0, and results are retrieved accordingly.
- Invalid or incomplete regular expressions invalidate the filter, and no results are retrieved.

4. Click Add.
5. As needed, repeat these steps to add additional filters. If filtering by more than one node fact, specify either Nodes must match all rules or Nodes can match any rule.

**Filtering nodes in your node list**

Filter your node list by node name or by PQL query to more easily inspect them.

**Filter your node list by node name**

Filter your nodes list by node name to inspect them as a group.

Select **Node name**, type in the word you want to filter by, and click **Submit**.

**Filter your nodes by PQL query**

Filter your nodes list using a common PQL query.

Filtering your nodes list by PQL query enables you to manage them by specific factors, such as by operating system, report status, or class.

Specify a target by doing one of the following:

- Enter a query that selects the target you want. See the Puppet Query Language (PQL) reference for more information.
- Click **Common queries**. Select one of the queries and replace the defaults in the braces ({} ) with values that specify the target you want.

<table>
<thead>
<tr>
<th>Target</th>
<th>PQL query</th>
</tr>
</thead>
<tbody>
<tr>
<td>All nodes</td>
<td>nodes[certname] { }</td>
</tr>
<tr>
<td>Nodes with a specific resource (example: httpd)</td>
<td>resources[certname] ( type = &quot;Service&quot; and title = &quot;httpd&quot; )</td>
</tr>
<tr>

</tbody>
</table>

### View the Puppet Services status monitor

The **Puppet Services status** monitor provides a visual overview of the current state of core services, and can be used to quickly determine whether an unresponsive or restarting service is causing an issue with your deployment.

A checkmark appears next to **Puppet Services status** if all applicable services are accepting requests. In the event that no data is available, a question mark appears next to the link. If one or more services is restarting or not accepting requests, a warning icon appears.

1. In the console, click **Status**.
2. Click **Puppet Services status** to open the monitor.

### puppet infrastructure status command

The **puppet infrastructure status command** displays errors and alerts from PE components and services.

The command reports separately on the master and any compilers or replicas in your environment. You must run the command as root.

### Viewing and managing packages

The **Packages** page in the console shows all packages in use across your infrastructure by name, version, and provider, as well as the number of instances of each package version in your infrastructure. Use the **Packages** page to quickly identify which nodes are impacted by packages you know are eligible for maintenance updates, security patches, and license renewals.

Package inventory reporting is available for all nodes with Puppet agent version 1.6.0 or later installed, including systems that are not actively managed by Puppet.

**Tip:** Packages are gathered from all available providers. The package data reported on the **Packages** page can also be obtained by using the **puppet resource** command to search for package.
Enable package data collection

Package data collection is disabled by default, so the Packages page in the console initially appears blank. In order to view a node's current package inventory, enable package data collection.

You can choose to collect package data on all your nodes, or just a subset. Any node with Puppet agent version 1.6.0 or later installed can report package data, including nodes that are not under active management with Puppet Enterprise.

1. In the console, click Node groups.
   - If you want to collect package data on all your nodes, click the PE Agent node group.
   - If you want to collect package data on a subset of your nodes, click Add group and create a new classification node group. Select PE Agent as the group's parent name. After the new node group is set up, use the Rules tab to dynamically add the relevant nodes.
2. Click Classes. In the Add new class field, select puppetenterprise::profile::agent and click Add class.
3. In the puppetenterprise::profile::agent class, set the Parameter to package_inventory_enabled and the Value to true. Click Add parameter, and commit changes.
4. Run Puppet to apply these changes to the nodes in your node group.

   Puppet enables package inventory collection on this Puppet run, and begins collecting package data and reporting it on the Packages page on each subsequent Puppet run.
5. Run Puppet a second time to begin collecting package data, then click Packages.

View and manage package inventory

To view and manage the complete inventory of packages on your systems, use the Packages page in the console.

Before you begin

Make sure you have enabled package data collection for the nodes you wish to view.

Tip: If all the nodes on which a certain package is installed are deactivated, but the nodes' specified node-purge-ttl period has not yet elapsed, instances of the package still appear in summary counts on the Packages page. To correct this issue, adjust the node-purge-ttl setting and run garbage collection.

1. Run Puppet to collect the latest package data from your nodes.
2. In the console, click Packages to view your package inventory. To narrow the list of packages, enter the name or partial name of a package in the Filter by package name field and click Apply.
3. Click any package name or version to enter the detail page for that package.
4. On a package's detail page, use the Version selector to locate nodes with a particular package version installed.
5. Use the Instances selector to locate nodes where the package is not managed with Puppet, or to view nodes on which a package instance is managed with Puppet.

   To quickly find the place in your manifest where a Puppet-managed package is declared, select a code path in the Instances selector and click Copy path.
6. To modify a package on a group of nodes:
   - If the package is managed with Puppet, select a code path in the Instances selector and click Copy path, then navigate to and update the manifest.
   - If the package is not managed with Puppet, click Run > Task and create a new task.

View package data collection metadata

The puppet_inventory_metadata fact reports whether package data collection is enabled on a node, and shows the time spent collecting package data on the node during the last Puppet run.

Before you begin

Make sure you have enabled package data collection for the nodes you wish to view.
1. Click **Node groups** and select the node group you created when enabling package data collection.
2. Click **Matching nodes** and select a node from the list.
3. On the node's inventory page, click **Facts** and locate `puppet_inventory_metadata` in the list.

   The fact value looks something like:

   ```json
   {
     "packages" : {
       "collection_enabled" : true,
       "last_collection_time" : "1.9149s"
     }
   }
   ```

### Disable package data collection

If you need to disable package data collection, set `package_inventory_enabled` to `false` and run Puppet twice.

1. Click **Node groups** and select the node group you used when enabling package data collection.
2. On the **Classes** tab, find the `puppet_enterprise::profile::agent` class, locate `package_inventory_enabled` parameter, and click **Edit**.
3. Change the **Value** of `package_inventory_enabled` to `false`, then commit changes.
4. Run Puppet to apply these changes to the nodes in your node group and disable package data collection.

   Package data is collected for a final time during this run.

5. Run Puppet a second time to purge package data from the impacted nodes' storage.

### Infrastructure reports

Each time Puppet runs on a node, it generates a report that provides information such as when the run took place, any issues encountered during the run, and the activity of resources on the node. These reports are collected on the **Reports** page in the console.

### Working with the reports table

The **Reports** page provides a summary view of key data from each report. Use this page to track recent node activity so you can audit your system and perform root cause analysis over time.

The reports table lists the number of resources on each node in each of the following states:

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Correction applied</strong></td>
<td>Number of resources that received a corrective change after Puppet identified resources that were out of sync with the applied catalog.</td>
</tr>
<tr>
<td><strong>Failed</strong></td>
<td>Number of resources that failed.</td>
</tr>
<tr>
<td><strong>Changed</strong></td>
<td>Number of resources that changed.</td>
</tr>
<tr>
<td><strong>Unchanged</strong></td>
<td>Number of resources that remained unchanged.</td>
</tr>
<tr>
<td><strong>No-op</strong></td>
<td>Number of resources that would have been changed if not run in no-op mode.</td>
</tr>
<tr>
<td><strong>Skipped</strong></td>
<td>Number of resources that were skipped because they depended on resources that failed.</td>
</tr>
</tbody>
</table>
Failed restarts

Number of resources that were supposed to restart but didn’t.

For example, if changes to one resource notify another resource to restart, and that resource doesn’t restart, a failed restart is reported. It’s an indirect failure that occurred in a resource that was otherwise unchanged.

The reports table also offers the following information:

- **No-op mode**: An indicator of whether the node was run in no-op mode.
- **Config retrieval**: Time spent retrieving the catalog for the node (in seconds).
- **Run time**: Time spent applying the catalog on the node (in seconds).

**Tip**: Report count caching is used to improve console performance. In some cases, caching might cause summary counts of available reports to be displayed inaccurately the first time the page is accessed after a fresh install.

**Filtering reports**

You can filter the list of reports displayed on the Reports page by run status and by node fact. If you set a run status filter, and also set a node fact filter, the table takes both filters into account, and shows only those reports matching both filters.

Clicking Remove filter removes all filters currently in effect.

The filters you set are persistent. If you set run status or fact filters on the Reports page, they continue to be applied to the table until they're changed or removed, even if you navigate to other pages in the console or log out. The persistent storage is associated with the browser tab, not your user account, and is cleared when you close the tab.

**Filter by node run status**

Filter reports to quickly focus on nodes with failures or change events by using the Filter by run status bar.

1. Select a run status (such as **No-op mode: with failures**). The table updates to reflect your filter selection.
2. To remove the run status filter, select **All run statuses**.

**Filter by node fact**

You can create a highly specific list of nodes for further investigation by using the fact filter tool.

For example, you can check that nodes you've updated have successfully changed, or find out the operating systems or IP addresses of a set of failed nodes to better understand the failure. You might also filter by facts to fulfill an auditor's request for information, such as the number of nodes running a particular version of software.

1. Click **Filter by fact value**. In the **Fact** field, select one of the available facts. An empty fact field is not allowed.

**Tip**: To see the facts and values reported by a node on its most recent run, click the node name in the **Run status** table, then select the node’s **Facts** tab.

© 2020 Puppet, Inc.
2. Select an Operator:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>is</td>
<td></td>
</tr>
<tr>
<td>!=</td>
<td>is not</td>
<td></td>
</tr>
<tr>
<td>~</td>
<td>matches a regular expression</td>
<td>Select this operator to use wildcards and other regular expressions if you want to find matching facts without having to specify the exact value.</td>
</tr>
<tr>
<td>~</td>
<td>does not match a regular expression (regex)</td>
<td></td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>Can be used only with facts that have a numeric value.</td>
</tr>
</tbody>
</table>

3. In the Value field, enter a value. Strings are case-sensitive, so make sure you use the correct case.

The filter displays an error if you use an invalid string operator (for example, selecting a numeric value operator such as >= and entering a non-numeric string such as pilsen as the value) or enter an invalid regular expression.

**Note:** If you enter an invalid or empty value in the Value field, PE takes the following action in order to avoid a filter error:

- Invalid or empty Boolean facts are processed as false, and results are retrieved accordingly.
- Invalid or empty numeric facts are processed as 0, and results are retrieved accordingly.
- Invalid or incomplete regular expressions invalidate the filter, and no results are retrieved.

4. Click Add.

5. As needed, repeat these steps to add additional filters. If filtering by more than one node fact, specify either Nodes must match all rules or Nodes can match any rule.

**Working with individual reports**

To examine a report in greater detail, click Report time. This opens a page that provides details for the node’s resources in three sections: Events, Log, and Metrics.

**Events**

The Events tab lists the events for each managed resource on the node, its status, whether correction was applied to the resource, and — if it changed — what it changed from and what it changed to. For example, a user or a file might change from absent to present.

To filter resources by event type, click Filter by event status and choose an event.

Sort resources by name or events by severity level, ascending or descending, by clicking the Resource or Events sorting controls.

To download the events data as a .csv file, click Export data. The filename is events-<node name>-<timestamp>.
Log

The **Log** tab lists errors, warnings, and notifications from the node's latest Puppet run.

Each message is assigned one of the following severity levels:

<table>
<thead>
<tr>
<th>Standard</th>
<th>Caution (yellow)</th>
<th>Warning (red)</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>warning</td>
<td>err</td>
</tr>
<tr>
<td>info</td>
<td>alert</td>
<td>emerg</td>
</tr>
<tr>
<td>notice</td>
<td></td>
<td>crit</td>
</tr>
</tbody>
</table>

To read the report chronologically, click the time sorting controls. To read it in order of issue severity, click the severity level sorting controls.

To download the log data as a `.csv` file, click Export data. The filename is `log-<node name>-<timestamp>`.

Metrics

The **Metrics** tab provides a summary of the key data from the node's latest Puppet run.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report submitted by:</td>
<td>The certname of the Puppet master that submitted the report to PuppetDB.</td>
</tr>
<tr>
<td>Puppet environment</td>
<td>The environment assigned to the node.</td>
</tr>
<tr>
<td>Puppet run</td>
<td>• The time that the Puppet run began &lt;br&gt; • The time that the Puppet master submitted the catalog&lt;br&gt; • The time that the Puppet run finished&lt;br&gt; • The time PuppetDB received the report&lt;br&gt; • The duration of the Puppet run&lt;br&gt; • The length of time to retrieve the catalog&lt;br&gt; • The length of time to apply the resources to the catalog</td>
</tr>
<tr>
<td>Catalog application</td>
<td>Information about the catalog application that produces the report: the config version that Puppet uses to match a specific catalog for a node to a specific Puppet run, the catalog UUID that identifies the catalog used to generate a report during a Puppet run, and whether the Puppet run used a cached catalog.</td>
</tr>
<tr>
<td>Resources</td>
<td>The total number of resources in the catalog.</td>
</tr>
<tr>
<td>Events</td>
<td>A list of event types and the total count for each one.</td>
</tr>
<tr>
<td>Top resource types</td>
<td>A list of the top resource types by time, in seconds, it took to be applied.</td>
</tr>
</tbody>
</table>
Analyzing changes across Puppet runs

The **Events** page in the console shows a summary of activity in your infrastructure. You can analyze the details of important changes, and investigate common causes behind related events. You can also examine specific class, node, and resource events, and find out what caused them to fail, change, or run as no-op.

**What is an event?**

An event occurs whenever PE attempts to modify an individual property of a given resource. Reviewing events lets you see detailed information about what has changed on your system, or what isn't working properly.

During a Puppet run, Puppet compares the current state of each property on each resource to the desired state for that property, as defined by the node's catalog. If Puppet successfully compares the states and the property is already in sync (in other words, if the current state is the desired state), Puppet moves on to the next resource without noting anything. Otherwise, it attempts some action and records an event, which appears in the report it sends to the Puppet master at the end of the run. These reports provide the data presented on the **Events** page in the console.

**Event types**

There are six types of event that can occur when Puppet reviews each property in your system and attempts to make any needed changes. If a property is already in sync with its catalog, no event is recorded: no news is good news in the world of events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failure</td>
<td>A property was out of sync; Puppet tried to make changes, but was unsuccessful.</td>
</tr>
<tr>
<td>Corrective change</td>
<td>Puppet found an inconsistency between the last applied catalog and a property's configuration, and corrected the property to match the catalog.</td>
</tr>
<tr>
<td>Intentional change</td>
<td>Puppet applied catalog changes to a property.</td>
</tr>
<tr>
<td>Corrective no-op</td>
<td>Puppet found an inconsistency between the last applied catalog and a property's configuration, but Puppet was instructed to not make changes on this resource, via either the <code>--noop</code> command-line option, the <code>noop</code> setting, or the <code>noop =&gt; true</code> metaparameter. Instead of making a corrective change, Puppet logs a corrective no-op event and reports the change it would have made.</td>
</tr>
<tr>
<td>Intentional no-op</td>
<td>Puppet would have applied catalog changes to a property., but Puppet was instructed to not make changes on this resource, via either the <code>--noop</code> command-line option, the <code>noop</code> setting, or the <code>noop =&gt; true</code> metaparameter. Instead of making an intentional change, Puppet logs an intentional no-op event and reports the change it would have made.</td>
</tr>
<tr>
<td>Event</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>Skip</td>
<td>A prerequisite for this resource was not met, so Puppet did not compare its current state to the desired state. This prerequisite is either one of the resource's dependencies or a timing limitation set with the <code>schedule</code> metaparameter. The resource might be in sync or out of sync; Puppet doesn't know yet. If the <code>schedule</code> metaparameter is set for a given resource, and the scheduled time hasn't arrived when the run happens, that resource logs a skip event on the Events page. This is true for a user-defined <code>schedule</code>, but does not apply to built-in scheduled tasks that happen weekly, daily, or at other intervals.</td>
</tr>
</tbody>
</table>

**Working with the Events page**

During times when your deployment is in a state of stability, with no changes being made and everything functioning optimally, the Events page reports little activity, and might not seem terribly interesting. But when change occurs—when packages require upgrades, when security concerns threaten, or when systems fail—the Events page helps you understand what's happening and where so you can react quickly.

The Events page fetches data when loading, and does not refresh—even if there's a Puppet run while you're on the page—until you close or reload the page. This ensures that shifting data won't disrupt an investigation.

You can see how recent the shown data is by checking the timestamp at the top of the page. Reload the page to update the data to the most recent events.

**Tip:** Keeping time synchronized by running NTP across your deployment helps the Events page produce accurate information. NTP is easily managed with PE, and setting it up is an excellent way to learn Puppet workflows.

**Monitoring infrastructure with the Events summary pane**

The Events page displays all events from the latest report of every responsive node in the deployment.

**Tip:** By default, PE considers a node unresponsive after one hour, but you can configure this setting to meet your needs by adjusting the `puppet_enterprise::console_services::no_longer_reporting_cutoff` parameter.

On the left side of the screen, the Events summary pane shows an overview of Puppet activity across your infrastructure. This data can help you rapidly assess the magnitude of any issue.

The Events summary pane is split into three categories—the Classes summary, Nodes summary, and Resources summary—to help you investigate how a change or failure event impacts your entire deployment.

**Gaining insight with the Events detail pane**

Clicking an item in the Events summary pane loads its details (and any sub-items) in the Events detail pane on the right of the screen. The summary pane on the left always shows the list of items from which the one in the detail pane on the right was chosen, to let you easily view similar items and compare their states.

Click any item in the the Classes summary, Nodes summary, or Resources summary to load more specific info into the detail pane and begin looking for the causes of notable events. Switch between perspectives to find the common threads among a group of failures or corrective changes, and follow them to a root cause.

**Analyzing changes and failures**

You can use the Events page to analyze the root causes of events resulting from a Puppet run. For example, to understand the cause of a failure after a Puppet run, select the class, node, or resource with a failure in the Events summary pane, and then review the details of the failure in the Events detail pane.
You can view additional details by clicking on the failed item in the in the **Events** detail pane.

Use the **Classes** summary, **Nodes** summary, and **Resources** summary to focus on the information you need. For example, if you’re concerned about a failed service, say Apache or MongoDB, you can start by looking into failed resources or classes. If you’re experiencing a geographic outage, you might start by drilling into failed node events.

### Understanding event display issues

In some special cases, events are not displayed as expected on the **Events** page. These cases are often caused by the way that the console receives data from other parts of Puppet Enterprise, but sometimes are due to the way your Puppet code is interpreted.

**Runs that restart PuppetDB are not displayed**

If a given Puppet run restarts PuppetDB, Puppet is not able to submit a run report from that run to PuppetDB because PuppetDB is not available. Because the **Events** page relies on data from PuppetDB, and PuppetDB reports are not queued, the **Events** page does not display any events from that run. Note that in such cases, a run report is available on the **Reports** page. Having a Puppet run restart PuppetDB is an unlikely scenario, but one that could arise in cases where some change to, say, a parameter in the `puppetdb` class causes the `pe-puppetdb` service to restart.

**Runs without a compiled catalog are not displayed**

If a run encounters a catastrophic failure where an error prevents a catalog from compiling, the **Events** page does not display any failures. This is because no events occurred.

**Simplified display for some resource types**

For resource types that take the `ensure` property, such as user or file resource types, the **Events** page displays a single event when the resource is first created. This is because Puppet has changed only one property (`ensure`), which sets all the baseline properties of that resource at the same time. For example, all of the properties of a given user are created when the user is added, just as if the user was added manually. If a later Puppet run changes properties of that user resource, each individual property change is shown as a separate event.

**Updated modes display without leading zeros**

When the `mode` attribute for a `file` resource is updated, and numeric notation is used, leading zeros are omitted in the **New Value** field on the **Events** page. For example, `0660` is shown as `660` and `0000` is shown as `0`.

### Collecting value analytics

The value API provides insight into time and money freed by PE automation.

The values API reports details about automated changes that PE makes to nodes, and provides an estimate of time freed by each type of change based on intelligent defaults or values you provide. You can also specify an average hourly salary and see an estimate of cost savings for all automated changes.

Default settings for time freed by each type of automated change are based on customer research. Defaults take into account time to triage, research, and fix issues, as well as context switching. You can specify `low`, `med`, or `high` values for time freed parameters, or provide an exact value based on averages in your business.

Follow these best practices to ensure your value analysis is accurate:

- Failed runs aren’t tallied by value analytics, so ensure that tasks, plans, and Puppet runs are processing normally.
- Query the endpoint on a regular basis to gather data over a period of time.

**GET /api/reports/value**

Use the `/value` endpoint to retrieve information about time and money freed by PE automation.

**Forming requests**

Requests to the value API must be well-formed HTTP(S) requests.
By default, the value API uses the standard HTTPS port for console communication, port 443. You can omit the port from requests unless you want to specify a different port.

**Authenticating**

You must authenticate requests to the value API using your Puppet CA certificate and an RBAC token. The RBAC token must have viewing permissions for the console.

A simple, authenticated API request without any parameters looks like this:

```
curl https://<HOSTNAME>/api/reports/value \
--cacert /etc/puppetlabs/puppet/ssl/certs/ca.pem \
-H "X-Authentication: <RBAC_TOKEN>"
```

**Query parameters**

The request accepts the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>averageHourlySalary</td>
<td>Numeric value specifying average hourly cost savings for automated work.</td>
<td>none</td>
</tr>
<tr>
<td>startDate</td>
<td>Date in yyyy-mm-dd format.</td>
<td>1 week ago +2 days</td>
</tr>
<tr>
<td>endDate</td>
<td>Date in yyyy-mm-dd format.</td>
<td>today -2 days</td>
</tr>
<tr>
<td>minutesFreedPerCorrectiveChange</td>
<td>low (90 minutes)</td>
<td>med</td>
</tr>
<tr>
<td></td>
<td>• med (180 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• high (360 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• any numeric value in minutes</td>
<td></td>
</tr>
<tr>
<td>minutesFreedPerIntentionalChange</td>
<td>low (30 min)</td>
<td>med</td>
</tr>
<tr>
<td></td>
<td>• med (90 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• high (180 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• any numeric value in minutes</td>
<td></td>
</tr>
<tr>
<td>minutesFreedPerTaskRun</td>
<td>low (30 minutes)</td>
<td>med</td>
</tr>
<tr>
<td></td>
<td>• med (90 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• high (180 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• any numeric value in minutes</td>
<td></td>
</tr>
<tr>
<td>minutesFreedPerPlanRun</td>
<td>low (90 minutes)</td>
<td>med</td>
</tr>
<tr>
<td></td>
<td>• med (180 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• high (360 minutes)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• any numeric value in minutes</td>
<td></td>
</tr>
</tbody>
</table>

**Response format**

The response is a JSON object that lists details about time and cost freed, using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>Start date for the reporting period.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>endDate</td>
<td>End date for the reporting period.</td>
</tr>
<tr>
<td>totalCorrectiveChanges</td>
<td>Total number of corrective changes made during the reporting period.</td>
</tr>
<tr>
<td>minutesFreedByCorrectiveChanges</td>
<td>Total number of minutes freed by automated changes that prevent drift during regular Puppet runs. The calculation is based on the average minutes saved per change, as specified by the minutesFreedPerCorrectiveChange query parameter.</td>
</tr>
<tr>
<td>totalIntentionalChanges</td>
<td>Total number of intentional changes made during the reporting period.</td>
</tr>
<tr>
<td>minutesFreedByIntentionalChanges</td>
<td>Total number of minutes freed by automated changes based on new values or Puppet code. This calculation is based on the average minutes saved per change, as specified by the minutesFreedPerIntentionalChange query parameter.</td>
</tr>
<tr>
<td>totalNodesAffectedByTaskRuns</td>
<td>Total number of nodes affected by successful task runs during the reporting period.</td>
</tr>
<tr>
<td>minutesFreedByTaskRuns</td>
<td>Total number of minutes freed by automated task runs. This calculation is based on the average minutes saved per task run, as specified by the minutesFreedPerTaskRun query parameter.</td>
</tr>
<tr>
<td>totalNodesAffectedByPlanRuns</td>
<td>Total number of nodes affected by successful plan runs during the reporting period.</td>
</tr>
<tr>
<td>minutesFreedByPlanRuns</td>
<td>Total number of minutes freed by automated plan runs. This calculation is based on the average minutes saved per plan run, as specified by the minutesFreedPerPlanRun query parameter.</td>
</tr>
<tr>
<td>totalMinutesFreed</td>
<td>Total number of minutes free by all automated changes.</td>
</tr>
<tr>
<td>totalDollarsSaved</td>
<td>If the query specified an averageHourlySalary, total cost savings for all automated changes.</td>
</tr>
</tbody>
</table>

**Examples**

To generate a report for specified dates using the default time freed values:

```bash
curl -G https://<HOSTNAME>/api/reports/value \
  --cacert /etc/puppetlabs/puppet/ssl/certs/ca.pem \ 
  -H "X-Authentication: <RBAC_TOKEN>" \ 
  --data-urlencode 'startDate=2020-07-08' \ 
  --data-urlencode 'endDate=2020-07-15'
```

Result:

```json
{
  "startDate": "2020-07-08",
  "endDate": "2020-07-15",
  "totalCorrectiveChanges": 0,
  "minutesFreedByCorrectiveChanges": 0,
}
```

© 2020 Puppet, Inc.
To generate cost savings using default report dates and time freed values:

```bash
curl -G https://<pe-console-fqdn>/api/reports/value
  --cacert /etc/puppetlabs/puppet/ssl/certs/ca.pem
  -H "X-Authentication: <rbac token>"
  --data-urlencode 'averageHourlySalary=40'
```

Result:

```json
{
  "startDate": "2020-07-08",
  "endDate": "2020-07-15",
  "totalCorrectiveChanges": 0,
  "minutesFreedByCorrectiveChanges": 0,
  "totalIntentionalChanges": 18,
  "minutesFreedByIntentionalChanges": 1620,
  "totalNodesAffectedByPlanRuns": 0,
  "totalNodesAffectedByTaskRuns": 0,
  "minutesFreedByPlanRuns": 0,
  "minutesFreedByTaskRuns": 0,
  "totalMinutesFreed": 1620,
}
```

To generate a report with custom values for time freed:

```bash
curl -G https://<pe-console-fqdn>/api/reports/value
  --cacert /etc/puppetlabs/puppet/ssl/certs/ca.pem
  -H "X-Authentication: $(cat ~/.puppetlabs/token)"
  --data-urlencode 'minutesFreedPerCorrectiveChange=10'
  --data-urlencode 'minutesFreedPerIntentionalChange=20'
  --data-urlencode 'minutesFreedPerTaskRun=30'
  --data-urlencode 'minutesFreedPerPlanRun=40'
```

Result:

```json
{
  "startDate": "2020-07-01",
  "endDate": "2020-07-08",
  "totalCorrectiveChanges": 1,
  "minutesFreedByCorrectiveChanges": 10,
  "totalIntentionalChanges": 2,
  "minutesFreedByIntentionalChanges": 40,
  "totalNodesAffectedByTaskRuns": 3,
  "minutesFreedByTaskRuns": 90,
  "totalNodesAffectedByPlanRuns": 4,
  "minutesFreedByPlanRuns": 160,
  "totalMinutesFreed": 300
}
```
Viewing and managing Puppet Server metrics

Puppet Server can provide performance and status metrics to external services for monitoring server health and performance over time.

You can track Puppet Server metrics by using:

• Customizable, networked Graphite and Grafana instances
• A built-in experimental developer dashboard
• Status API endpoints

**Note:** None of these methods are officially supported. The Grafanadash and Puppet-graphite modules referenced in this document are not Puppet-supported modules; they are mentioned for testing and demonstration purposes only. The developer dashboard is a tech preview. Both the Grafana and developer dashboard methods take advantage of the Status API, including some endpoints that are also a tech preview.

- **Getting started with Graphite** on page 266
  Puppet Enterprise can export many metrics to Graphite, a third-party monitoring application that stores real-time metrics and provides customizable ways to view them. After Graphite support is enabled, Puppet Server exports a set of metrics by default that is designed to be immediately useful to Puppet administrators.

- **Available Graphite metrics** on page 270
  These HTTP and Puppet profiler metrics are available from the Puppet Server and can be added to your metrics reporting.

**Getting started with Graphite**

Puppet Enterprise can export many metrics to Graphite, a third-party monitoring application that stores real-time metrics and provides customizable ways to view them. After Graphite support is enabled, Puppet Server exports a set of metrics by default that is designed to be immediately useful to Puppet administrators.

**Note:** A Graphite setup is deeply customizable and can report many different Puppet Server metrics on demand. However, it requires considerable configuration and additional server resources. For an easier, but more limited, web-based dashboard of Puppet Server metrics built into Puppet Server, use the developer dashboard. To retrieve metrics manually via HTTP, use the Status API.

To use Graphite with Puppet Enterprise, you must:

- Install and configure a Graphite server.
- Enable Puppet Server's Graphite support

Grafana provides a web-based customizable dashboard that's compatible with Graphite, and the Grafanadash module installs and configures it by default.

**Using the Grafanadash module**

The Grafanadash module quickly installs and configures a basic test instance of Graphite with the Grafana extension. When installed on a dedicated Puppet agent, this module provides a quick demonstration of how Graphite and Grafana can consume and display Puppet Server metrics.

**CAUTION:** The Grafanadash module referenced in this document is not a Puppet-supported module; it is for testing and demonstration purposes only. It is tested against CentOS 7 only. Also, install this module on a dedicated agent only. Do not install it on the Puppet master, because the module makes security policy changes that are inappropriate for a Puppet master:

- SELinux can cause issues with Graphite and Grafana, so the module temporarily disables SELinux. If you reboot the machine after using the module to install Graphite, you must disable SELinux again and restart the Apache service to use Graphite and Grafana.
- The module disables the iptables firewall and enables cross-origin resource sharing on Apache, which are potential security risks.
**Installing the Grafanadash module**

Install the Grafanadash module on a *nix agent. The module's `grafanadash::dev` class installs and configures a Graphite server, the Grafana extension, and a default dashboard.

1. Install a *nix PE agent to serve as the Graphite server.
2. As root on the Puppet agent node, run `puppet module install puppetlabs-grafanadash`.
3. As root on the Puppet agent node, run `puppet apply -e 'include grafanadash::dev'`.

**Running Grafana**

Grafana is a dashboard that can interpret and visualize Puppet Server metrics over time, but you must configure it to do so.

Grafana runs as a web dashboard, and the Grafanadash module configures it at port 10000 by default. However, there are no Puppet metrics displayed by default. You must create a metrics dashboard to view Puppet's metrics in Grafana, or edit and import a JSON-based dashboard such as the sample Grafana dashboard that we provide.

1. In a web browser on a computer that can reach the Puppet agent node, navigate to `http://<AGENT'S HOSTNAME>:10000`.
2. Open the `sample_metrics_dashboard.json` file in a text editor on the same computer you're using to access Grafana.
3. Throughout the file, replace our sample setting of `master.example.com` with the hostname of your Puppet master. This value must be used as the `metrics_server_id` setting, as configured below.
4. Save the file.
5. In the Grafana UI, click **search** (the folder icon), then **Import**, then **Browse**.
6. Navigate to and select the edited JSON file.

This loads a dashboard with nine graphs that display various metrics exported from the Puppet Server to the Graphite server. However, these graphs remain empty until you enable Puppet Server's Graphite metrics.

**Related information**

*Sample Grafana dashboard graphs* on page 267

Use the sample Grafana dashboard as your starting point and customize it to suit your needs. You can click on the title of any graph, and then click **edit** to adjust the graphs as you see fit.

**Enabling Puppet Server's Graphite support**

Use the PE Master node group in the console to configure Puppet Server's metrics output settings.

1. In the console, click **Node groups**, and in the **PE Infrastructure** group, select the **PE Master** group.
2. On the **Classes** tab, in the `puppet_enterprise::profile::master` class, add these parameters:
   a) Set `metrics_graphite_enabled` to `true` (default is `false`).
   b) Set `metrics_server_id` to the Puppet master hostname.
   c) Set `metrics_graphite_host` to the hostname for the agent node on which you're running Graphite and Grafana.
   d) Set `metrics_graphite_update_interval_seconds` to a value to set Graphite's update frequency in seconds. This setting is optional, and the default value is `60`.
3. Verify that these parameters are set to their default values, unless your Graphite server uses a non-standard port:
   a) Set `metrics_jmx_enabled` to `true` (default value).
   b) Set `metrics_graphite_port` to `2003` (default value) or the Graphite port on your Graphite server.
   c) Set `profiler_enabled` to `true` (default value).
4. Commit changes.

**Sample Grafana dashboard graphs**

Use the sample Grafana dashboard as your starting point and customize it to suit your needs. You can click on the title of any graph, and then click **edit** to adjust the graphs as you see fit.

*Sample Grafana dashboard code*

© 2020 Puppet, Inc.
<table>
<thead>
<tr>
<th>Graph name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active requests</td>
<td>This graph serves as a &quot;health check&quot; for the Puppet Server. It shows a flat line that represents the number of CPUs you have in your system, a metric that indicates the total number of HTTP requests actively being processed by the server at any moment in time, and a rolling average of the number of active requests. If the number of requests being processed exceeds the number of CPUs for any significant length of time, your server might be receiving more requests than it can efficiently process.</td>
</tr>
<tr>
<td>Request durations</td>
<td>This graph breaks down the average response times for different types of requests made by Puppet agents. This indicates how expensive catalog and report requests are compared to the other types of requests. It also provides a way to see changes in catalog compilation times when you modify your Puppet code. A sharp curve upward for all of the types of requests indicates an overloaded server, and they should trend downward after reducing the load on the server.</td>
</tr>
<tr>
<td>Request ratios</td>
<td>This graph shows how many requests of each type that Puppet Server has handled. Under normal circumstances, you should see about the same number of catalog, node, or report requests, because these all happen one time per agent run. The number of file and file metadata requests correlate to how many remote file resources are in the agents' catalogs.</td>
</tr>
<tr>
<td>External HTTP Communications</td>
<td>This graph tracks the amount of time it takes Puppet Server to send data and requests for common operations to, and receive responses from, external HTTP services, such as PuppetDB.</td>
</tr>
<tr>
<td>File Sync</td>
<td>This graph tracks how long Puppet Server spends on File Sync operations, for both its storage and client services.</td>
</tr>
<tr>
<td>Graph name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>JRubies</td>
<td>This graph tracks how many JRubies are in use, how many are free, the mean number of free JRubies, and the mean number of requested JRubies. If the number of free JRubies is often less than one, or the mean number of free JRubies is less than one, Puppet Server is requesting and consuming more JRubies than are available. This overload reduces Puppet Server's performance. While this might simply be a symptom of an under-resourced server, it can also be caused by poorly optimized Puppet code or bottlenecks in the server's communications with PuppetDB if it is in use. If catalog compilation times have increased but PuppetDB performance remains the same, examine your Puppet code for potentially unoptimized code. If PuppetDB communication times have increased, tune PuppetDB for better performance or allocate more resources to it. If neither catalog compilation nor PuppetDB communication times are degraded, the Puppet Server process might be under-resourced on your server. If you have available CPU time and memory, increase the number of JRuby instances to allow it to allocate more JRubies. Otherwise, consider adding additional compilers to distribute the catalog compilation load.</td>
</tr>
<tr>
<td>JRuby Timers</td>
<td>This graph tracks several JRuby pool metrics.</td>
</tr>
<tr>
<td></td>
<td>• The borrow time represents the mean amount of time that Puppet Server uses (&quot;borrows&quot;) each JRuby from the pool.</td>
</tr>
<tr>
<td></td>
<td>• The wait time represents the total amount of time that Puppet Server waits for a free JRuby instance.</td>
</tr>
<tr>
<td></td>
<td>• The lock held time represents the amount of time that Puppet Server holds a lock on the pool, during which JRubies cannot be borrowed. This occurs while Puppet Server synchronizes code for File Sync.</td>
</tr>
<tr>
<td></td>
<td>• The lock wait time represents the amount of time that Puppet Server waits to acquire a lock on the pool.</td>
</tr>
<tr>
<td></td>
<td>These metrics help identify sources of potential JRuby allocation bottlenecks.</td>
</tr>
<tr>
<td>Memory Usage</td>
<td>This graph tracks how much heap and non-heap memory that Puppet Server uses.</td>
</tr>
<tr>
<td>Compilation</td>
<td>This graph breaks catalog compilation down into various phases to show how expensive each phase is on the master.</td>
</tr>
</tbody>
</table>

**Example Grafana dashboard excerpt**

The following example shows only the `targets` parameter of a dashboard to demonstrate the full names of Puppet's exported Graphite metrics (assuming the Puppet Server instance has a domain of `master.example.com`) and a way to add targets directly to an exported Grafana dashboard's JSON content.

```json
"panels": [
  {
    "span": 4,
```
"editable": true,
"type": "graphite",

...\

"targets": [
  {
    "target": "alias(puppetlabs.master.example.com.num-cpus,'num cpus')"
  },
  {
    "target": "alias(puppetlabs.master.example.com.http.active-requests.count,'active requests')"
  },
  {
    "target": "alias(puppetlabs.master.example.com.http.active-histo.mean,'average')"
  }
],
"aliasColors": {},
"aliasYAxis": {},
"title": "Active Requests"
]

See the sample Grafana dashboard for a detailed example of how a Grafana dashboard accesses these exported Graphite metrics.

Available Graphite metrics

These HTTP and Puppet profiler metrics are available from the Puppet Server and can be added to your metrics reporting.

Graphite metrics properties

Each metric is prefixed with puppetlabs.<MASTER-HOSTNAME>; for instance, the Grafana dashboard file refers to the num-cpus metric as puppetlabs.<MASTER-HOSTNAME>.num-cpus.

Additionally, metrics might be suffixed by fields, such as count or mean, that return more specific data points. For instance, the puppetlabs.<MASTER-HOSTNAME>.compiler.mean metric returns only the mean length of time it takes Puppet Server to compile a catalog.

To aid with reference, metrics in the list below are segmented into three groups:

- **Statistical metrics**: Metrics that have all eight of these statistical analysis fields, in addition to the top-level metric:
  - max: Its maximum measured value.
  - min: Its minimum measured value.
  - mean: Its mean, or average, value.
  - stddev: Its standard deviation from the mean.
  - count: An incremental counter.
  - p50: The value of its 50th percentile, or median.
  - p75: The value of its 75th percentile.
  - p95: The value of its 95th percentile.
- **Counters only**: Metrics that only count a value, or only have a count field.
- **Other**: Metrics that have unique sets of available fields.

Note:

Puppet Server can export many metrics—so many that past versions of Puppet Enterprise could overwhelm Grafana servers. As of Puppet Enterprise 2016.4, Puppet Server exports only a subset of its available metrics by default. This
set is designed to report the most relevant Puppet Server metrics for administrators monitoring its performance and stability.

To add to the default list of exported metrics, see Modifying Puppet Server’s exported metrics.

Puppet Server exports each metric in the lists below by default.

**Statistical metrics**

**Compiler metrics:**

- puppetlabs.<MASTER-HOSTNAME>.compiler: The time spent compiling catalogs. This metric represents the sum of the compiler.compile, static_compile, find_facts, and find_node fields.
  
- puppetlabs.<MASTER-HOSTNAME>.compiler.compile: The total time spent compiling dynamic (non-static) catalogs.

  To measure specific nodes and environments, see Modifying Puppet Server’s exported metrics.

- puppetlabs.<MASTER-HOSTNAME>.compiler.find_facts: The time spent parsing facts.

- puppetlabs.<MASTER-HOSTNAME>.compiler.find_node: The time spent retrieving node data. If the Node Classifier (or another ENC) is configured, this includes the time spent communicating with it.

- puppetlabs.<MASTER-HOSTNAME>.compiler.static_compile: The time spent compiling static catalogs.

- puppetlabs.<MASTER-HOSTNAME>.compiler.static_compile_inlining: The time spent inlining metadata for static catalogs.

- puppetlabs.<MASTER-HOSTNAME>.compiler.static_compile_postprocessing: The time spent post-processing static catalogs.

**File sync metrics:**

- puppetlabs.<MASTER-HOSTNAME>.file-sync-client.clone-timer: The time spent by file sync clients on compilers initially cloning repositories on the master.

- puppetlabs.<MASTER-HOSTNAME>.file-sync-client.fetch-timer: The time spent by file sync clients on compilers fetching repository updates from the master.

- puppetlabs.<MASTER-HOSTNAME>.file-sync-client.sync-clean-check-timer: The time spent by file sync clients on compilers checking whether the repositories are clean.

- puppetlabs.<MASTER-HOSTNAME>.file-sync-client.sync-timer: The time spent by file sync clients on compilers synchronizing code from the private datadir to the live codedir.

- puppetlabs.<MASTER-HOSTNAME>.file-sync-storage.commit-add-rm-timer

- puppetlabs.<MASTER-HOSTNAME>.file-sync-storage.commit-timer: The time spent committing code on the master into the file sync repository.

**Function metrics:**

- puppetlabs.<MASTER-HOSTNAME>.functions: The amount of time during catalog compilation spent in function calls. The functions metric can also report any of the statistical metrics fields for a single function by specifying the function name as a field.

  For example, to report the mean time spent in a function call during catalog compilation, use puppetlabs.<MASTER-HOSTNAME>.functions.<FUNCTION-NAME>.mean.

**HTTP metrics:**

- puppetlabs.<MASTER-HOSTNAME>.http.active-histo: A histogram of active HTTP requests over time.

- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-catalog-/*/-requests: The time Puppet Server has spent handling catalog requests, including time spent waiting for an available JRuby instance.

- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-environment-/*/-requests: The time Puppet Server has spent handling environment requests, including time spent waiting for an available JRuby instance.
• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-environment_classes-/*/-requests: The time spent handling requests to the environment_classes API endpoint, which the Node Classifier uses to refresh classes.

• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-environments-requests: The time spent handling requests to the environments API endpoint requests made by the Orchestrator.

The following metrics measure the time spent handling file-related API endpoints:

• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_bucket_file-/*/-requests
• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_content-/*/-requests
• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_metadata-/*/-requests
• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_metadatas-/*/-requests

• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-node-/*/-requests: The time spent handling node requests, which are sent to the Node Classifier. A bottleneck here might indicate an issue with the Node Classifier or PuppetDB.

• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-report-/*/-requests: The time spent handling report requests. A bottleneck here might indicate an issue with PuppetDB.

• puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-static_file_content-/*/-requests: The time spent handling requests to the static_file_content API endpoint used by Direct Puppet with file sync.

JRuby metrics: Puppet Server uses an embedded JRuby interpreter to execute Ruby code. JRuby spawns parallel instances known as JRubies to execute Ruby code, which occurs during most Puppet Server activities. See Tuning JRuby on Puppet Server for details on adjusting JRuby settings.

• puppetlabs.<MASTER-HOSTNAME>.jruby.borrow-timer: The time spent with a borrowed JRuby.
• puppetlabs.<MASTER-HOSTNAME>.jruby.free-jrubies-histo: A histogram of free JRubies over time. This metric's average value must be greater than 1; if it isn't, more JRubies or another compiler might be needed to keep up with requests.
• puppetlabs.<MASTER-HOSTNAME>.jruby.lock-held-timer: The time spent holding the JRuby lock.
• puppetlabs.<MASTER-HOSTNAME>.jruby.lock-wait-timer: The time spent waiting to acquire the JRuby lock.
• puppetlabs.<MASTER-HOSTNAME>.jruby.requested-jrubies-histo: A histogram of requested JRubies over time. This increases as the number of free JRubies, or the free-jrubies-histo metric, decreases, which can suggest that the server's capacity is being depleted.
• puppetlabs.<MASTER-HOSTNAME>.jruby.wait-timer: The time spent waiting to borrow a JRuby.

PuppetDB metrics: The following metrics measure the time that Puppet Server spends sending or receiving data from PuppetDB.

• puppetlabs.<MASTER-HOSTNAME>.puppetdb.catalog.save
• puppetlabs.<MASTER-HOSTNAME>.puppetdb.command.submit
• puppetlabs.<MASTER-HOSTNAME>.puppetdb.facts.find
• puppetlabs.<MASTER-HOSTNAME>.puppetdb.facts.search
• puppetlabs.<MASTER-HOSTNAME>.puppetdb.report.process
• puppetlabs.<MASTER-HOSTNAME>.puppetdb.resource.search

Counters only

HTTP metrics:

• puppetlabs.<MASTER-HOSTNAME>.http.active-requests: The number of active HTTP requests.
The following counter metrics report the percentage of each HTTP API endpoint's share of total handled HTTP requests.

- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-catalog-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-environment-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-environment_classes-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-environments-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_bucket_file-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_content-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_metadata-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-file_metadatas-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-node-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-report-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-resource_type-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-resource_types-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-static_file_content-/*/-percentage
- puppetlabs.<MASTER-HOSTNAME>.http.puppet-v3-status-/*/-percentage

- puppetlabs.<MASTER-HOSTNAME>.http.total-requests: The total requests handled by Puppet Server.

**JRuby metrics:**

- puppetlabs.<MASTER-HOSTNAME>.jruby.borrow-count: The number of successfully borrowed JRubies.
- puppetlabs.<MASTER-HOSTNAME>.jruby.borrow-retry-count: The number of attempts to borrow a JRuby that must be retried.
- puppetlabs.<MASTER-HOSTNAME>.jruby.borrow-timeout-count: The number of attempts to borrow a JRuby that resulted in a timeout.
- puppetlabs.<MASTER-HOSTNAME>.jruby.request-count: The number of requested JRubies.
- puppetlabs.<MASTER-HOSTNAME>.jruby.return-count: The number of JRubies successfully returned to the pool.
- puppetlabs.<MASTER-HOSTNAME>.jruby.num-free-jrubies: The number of free JRuby instances. If this number is often 0, more requests are coming in than the server has available JRuby instances. To alleviate this, increase the number of JRuby instances on the Server or add additional compilers.

**Other metrics**

These metrics measure raw resource availability and capacity.

- puppetlabs.<MASTER-HOSTNAME>.num-cpus: The number of available CPUs on the server.
- puppetlabs.<MASTER-HOSTNAME>.uptime: The Puppet Server process's uptime.
• Total, heap, and non-heap memory that's committed (committed), initialized (init), and used (used), and the maximum amount of memory that can be used (max).
  • puppetlabs.<MASTER-HOSTNAME>.memory.total.committed
  • puppetlabs.<MASTER-HOSTNAME>.memory.total.init
  • puppetlabs.<MASTER-HOSTNAME>.memory.total.used
  • puppetlabs.<MASTER-HOSTNAME>.memory.total.max
  • puppetlabs.<MASTER-HOSTNAME>.memory.heap.committed
  • puppetlabs.<MASTER-HOSTNAME>.memory.heap.init
  • puppetlabs.<MASTER-HOSTNAME>.memory.heap.used
  • puppetlabs.<MASTER-HOSTNAME>.memory.heap.max
  • puppetlabs.<MASTER-HOSTNAME>.memory.non-heap.committed
  • puppetlabs.<MASTER-HOSTNAME>.memory.non-heap.init
  • puppetlabs.<MASTER-HOSTNAME>.memory.non-heap.used
  • puppetlabs.<MASTER-HOSTNAME>.memory.non-heap.max

Related information

Modifying exported metrics on page 274

In addition to the default metrics, you can also export metrics measuring specific environments and nodes managed by Puppet Server.

Modifying exported metrics

In addition to the default metrics, you can also export metrics measuring specific environments and nodes managed by Puppet Server.

The $metrics_puppetserver_metrics_allowed class parameter in the puppet_enterprise::profile::master class takes an array of metrics as strings. To export additional metrics, add them to this array.

Optional metrics include:
  • compiler.compile.<ENVIRONMENT> and compiler.compile.<ENVIRONMENT>.<NODE-NAME>, and all statistical fields suffixed to these (such as compiler.compile.<ENVIRONMENT>.mean).
  • compiler.compile.evaluate_resources.<RESOURCE>: Time spent evaluating a specific resource during catalog compilation.

Omit the puppetlabs.<MASTER-HOSTNAME> prefix and field suffixes (such as .count or .mean) from metrics. Instead, suffix the environment or node name as a field to the metric.

1. For example, to track the compilation time for the production environment, add compiler.compile.production to the metrics-allowed list.

2. To track only the my.node.localdomain node in the production environment, add compiler.compile.production.my.node.localdomain to the metrics-allowed list.

Status API

The status API allows you to check the health of PE components and services. It can be useful for automated monitoring of your infrastructure, removing unhealthy service instances from a load-balanced pool, checking configuration values, or troubleshooting issues in PE.

You can check the overall health of the console service, as well as the health of the individual services within the console service:
  • Activity service
  • Classifier service
  • PuppetDB
  • Puppet Server
  • Role-based access control (RBAC) service
• Code Manager service

The endpoints provide overview health information in an overall healthy/error/unknown status field, and fine-detail information such as the availability of the database, the health of other required services, or connectivity to the master.

• Authenticating to the status API on page 275

Token-based authentication is not required to access the status API. You can choose to authenticate requests by using whitelisted certificates, or can access the API without authentication via HTTP.

• Forming requests to the status API on page 275

The HTTPS status endpoints are available on the console services API server, which uses port 4433 by default.

• JSON endpoints on page 276

These two endpoints provide machine-consumable information about running services. They are intended for scripting and integration with other services.

• Activity service plaintext endpoints on page 278

The activity service plaintext endpoints are designed for load balancers that don't support any kind of JSON parsing or parameter setting. They return simple string bodies (either the state of the service in question or a simple error message) and a status code relevant to the status result.

• Metrics endpoints on page 279

Puppet Server is capable of tracking advanced metrics to give you additional insight into its performance and health.

• The metrics API on page 285

Puppet Enterprise includes an optional, enabled-by-default web endpoint for Java Management Extension (JMX) metrics, namely managed beans (MBeans).

Related information

API index on page 33

APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

**Authenticating to the status API**

Token-based authentication is not required to access the status API. You can choose to authenticate requests by using whitelisted certificates, or can access the API without authentication via HTTP.

You can authenticate requests using a certificate listed in RBAC's certificate whitelist, located at /etc/puppetlabs/console-services/rbac-certificate-whitelist. The certificate whitelist is a simple, flat file consisting of certnames that match the host, for example:

```text
node1.example
node2.example
node3.example
```

**Note:** If you edit the certificate whitelist, you must reload the pe-console-services service (run `sudo service pe-console-services reload`) for your changes to take effect.

The status API's endpoints can be served over HTTP, which does not require any authentication. This is disabled by default.

**Tip:** To use HTTP, locate the PE Console node group in the console, and in the puppet_enterprise::profile::console class, set `console_services_plaintext_status_enabled` to `true`.

**Forming requests to the status API**

The HTTPS status endpoints are available on the console services API server, which uses port 4433 by default.

The path prefix is `/status`, so, for example, the URL to get the statuses for all services as JSON is `https://<DNS NAME OF YOUR CONSOLE HOST>:4433/status/v1/services`.

To access that URL using curl commands, run:
Bash

```
cert="${puppet config print hostcert}"  
cacert="${puppet config print localcacert}"  
key="${puppet config print hostprivkey}"  
uri="${puppet config print server}:4433/status/v1/services"

curl --cert "$cert" --cacert "$cacert" --key "$key" "$uri"
```

If enabled, the HTTP status endpoints are available on port 8123. See Authenticating to the status API on page 275 to enable HTTP.

**Tip:** To change the port, locate the PE Console node group in the console, and in the puppet_enterprise::profile::console class, set the console_services_plaintext_status_port parameter to your desired port number.

### JSON endpoints

These two endpoints provide machine-consumable information about running services. They are intended for scripting and integration with other services.

**GET /status/v1/services**

Use the /services endpoint to retrieve the statuses of all PE services.

The content type for this endpoint is application/json; charset=utf-8.

**Query parameters**

The request accepts the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>How thorough of a check to run. Set to critical, debug, or info (default).</td>
</tr>
<tr>
<td>timeout</td>
<td>Specified in seconds; defaults to 30.</td>
</tr>
</tbody>
</table>

**Response format**

The response is a JSON object that lists details about the services, using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_version</td>
<td>Package version of the JAR file containing a given service.</td>
</tr>
<tr>
<td>service_status_version</td>
<td>The version of the API used to report the status of the service.</td>
</tr>
<tr>
<td>detail_level</td>
<td>Can be critical, debug, or info.</td>
</tr>
<tr>
<td>state</td>
<td>Can be running, error, or unknown.</td>
</tr>
<tr>
<td>status</td>
<td>An object with the service’s status details. Usually only relevant for error and unknown states.</td>
</tr>
<tr>
<td>active_alerts</td>
<td>An array of objects containing severity and a message about your replication from pglogical if you have replication enabled; otherwise, it's an empty array.</td>
</tr>
</tbody>
</table>

For example:

```
{"rbac-service": {"service_version": "1.8.11-SNAPSHOT"},
```
"service_status_version": 1,
"detail_level": "info",
"state": "running",
"status": {
  "activity_up": true,
  "db_up": true,
  "db_pool": { "state": "ready" },
  "replication": { "mode": "none", "status": "none" }
},
"active_alerts": [],
"service_name": "rbac-service"

"classifier-service": {
  "service_version": "1.8.11-SNAPSHOT",
  "service_status_version": 1,
  "detail_level": "info",
  "state": "running",
  "status": {
    "activity_up": true,
    "db_up": true,
    "db_pool": { "state": "ready" },
    "replication": { "mode": "none", "status": "none" }
  },
  "active_alerts": [],
  "service_name": "classifier-service"
}

Response codes

The server uses the following response codes:

- 200 if and only if all services report a status of running
- 503 if any service’s status is unknown or error
- 400 if a level parameter is set but is invalid (not critical, debug, or info)

GET /status/v1/services/<SERVICE NAME>

Use the /services/<SERVICE NAME> endpoint to retrieve the status of a particular PE service.

The content type for this endpoint is application/json; charset=utf-8.

Query parameters

The request accepts the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>How thorough of a check to run. Set to critical, debug, or info (default).</td>
</tr>
<tr>
<td>timeout</td>
<td>Specified in seconds; defaults to 30.</td>
</tr>
</tbody>
</table>

Response format

The response is a JSON object that lists details about the service, using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_version</td>
<td>Package version of the JAR file containing a given service.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>service_status_version</td>
<td>The version of the API used to report the status of the service.</td>
</tr>
<tr>
<td>detail_level</td>
<td>Can be critical, debug, or info.</td>
</tr>
<tr>
<td>state</td>
<td>Can be running, error, or unknown.</td>
</tr>
<tr>
<td>status</td>
<td>An object with the service’s status details. Usually only relevant for error and unknown states.</td>
</tr>
<tr>
<td>active_alerts</td>
<td>An array of objects containing severity and a message about your replication from pglogical if you have replication enabled; otherwise, it's an empty array.</td>
</tr>
</tbody>
</table>

For example:

```json
{"rbac-service": {"service_version": "1.8.11-SNAPSHOT", "service_status_version": 1, "detail_level": "info", "state": "running", "status": { "activity_up": true, "db_up": true, "db_pool": { "state": "ready" }, "replication": { "mode": "none", "status": "none" } }, "active_alerts": []},
```

**Response codes**

The server uses the following response codes:

- 200 if and only if all services report a status of running
- 503 if any service’s status is unknown or error
- 400 if a level parameter is set but is invalid (not critical, debug, or info)
- 404 if no service named `<SERVICE NAME>` is found

**Activity service plaintext endpoints**

The activity service plaintext endpoints are designed for load balancers that don’t support any kind of JSON parsing or parameter setting. They return simple string bodies (either the state of the service in question or a simple error message) and a status code relevant to the status result.

**GET /status/v1/simple**

The `/status/v1/simple` returns a status that reflects all services the status service knows about.

The content type for this endpoint is `text/plain; charset=utf-8`.

**Query parameters**

No parameters are supported. Defaults to using the critical status level.

**Response codes**

The server uses the following response codes:

- 200 if and only if all services report a status of running
- 503 if any service’s status is unknown or error
**Possible responses**

The endpoint returns a status that reflects all services it knows about. It decides on what status to report using the following logic:

- **running** if and only if all services are running
- **error** if any service reports an error
- **unknown** if any service reports an unknown and no services report an error

**GET /status/v1/simple/<SERVICE NAME>**

The /status/v1/simple/<SERVICE NAME> endpoint returns the plaintext status of the specified service, such as rbac-service or classifier-service.

The content type for this endpoint is text/plain; charset=utf-8.

**Query parameters**

No parameters are supported. Defaults to using the critical status level.

**Response codes**

The server uses the following response codes:

- 200 if and only if all services report a status of running
- 503 if any service’s status is unknown or error
- 404 if no service named <SERVICE NAME> is found

**Possible responses**

The endpoint returns a status that reflects all services it knows about. It decides on what status to report using the following logic:

- **running** if and only if all services are running
- **error** if any service reports an error
- **unknown** if any service reports an unknown and no services report an error
- **not found: <SERVICENAME>** if any service can’t be found

**Metrics endpoints**

Puppet Server is capable of tracking advanced metrics to give you additional insight into its performance and health.

The HTTPS metrics endpoints are available on port 8140 of the master server:

**Bash**

```
uri="https://$(puppet config print server):8140/status/v1/services"
curl --insecure "$uri"
```

**Note:** These API endpoints are a tech preview. The metrics described here are returned only when passing the `level=debug` URL parameter, and the structure of the returned data might change in future versions.

These metrics fall into three categories:

- JRuby metrics (/status/v1/services/pe-jruby-metrics)
- HTTP route metrics (/status/v1/services/pe-master)
- Catalog compilation profiler metrics (/status/v1/services/pe-puppet-profiler)

All of these metrics reflect data for the lifetime of the current Puppet Server process and reset whenever the service is restarted. Any time-related metrics report milliseconds unless otherwise noted.
Like the standard status endpoints, the metrics endpoints return machine-consumable information about running services. This JSON response includes the same keys returned by a standard status endpoint request (see JSON endpoints). Each endpoint also returns additional keys in an experimental section.

GET /status/v1/services/pe-jruby-metrics
The /status/v1/services/pe-jruby-metrics endpoint returns JSON containing information about the JRuby pools from which Puppet Server fulfills agent requests.

You must query it at port 8140 and append the level=debug URL parameter.

Query parameters
No parameters are supported. Defaults to using the critical status level.

Response codes
The server uses the following response codes:
- 200 if and only if all services report a status of running
- 503 if any service’s status is unknown or error

Response keys
The metrics are returned in two subsections of the experimental section: jruby-pool-lock-status and metrics.

The response's experimental/jruby-pool-lock-status section contains the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>current-state</td>
<td>The state of the JRuby pool lock, which should be either :not-in-use (unlocked), :requested (waiting for lock), or :acquired (locked).</td>
</tr>
<tr>
<td>last-change-time</td>
<td>The date and time of the last current-state update, formatted as an ISO 8601 combined date and time in UTC.</td>
</tr>
</tbody>
</table>

The response's experimental/metrics section contains the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>average-borrow-time</td>
<td>The average amount of time a JRuby instance spends handling requests, calculated by dividing the total duration in milliseconds of the borrowed-instances value by the borrow-count value.</td>
</tr>
<tr>
<td>average-free-jrubies</td>
<td>The average number of JRuby instances that are not in use over the Puppet Server process’s lifetime.</td>
</tr>
<tr>
<td>average-lock-held-time</td>
<td>The average time the JRuby pool held a lock, starting when the value of jruby-pool-lock-status/current-state changed to :acquired. This time mostly represents file sync syncing code into the live codedir, and is calculated by dividing the total length of time that Puppet Server held the lock by the value of num-pool-locks.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>average-lock-wait-time</td>
<td>The average time Puppet Server spent waiting to lock the JRuby pool, starting when the value of jruby-pool-lock-status/current-state changed to:requested. This time mostly represents how long Puppet Server takes to fulfill agent requests, and is calculated by dividing the total length of time that Puppet Server waits for locks by the value of num-pool-locks.</td>
</tr>
<tr>
<td>average-requested-jrubies</td>
<td>The average number of requests waiting on an available JRuby instance over the Puppet Server process’s lifetime.</td>
</tr>
<tr>
<td>average-wait-time</td>
<td>The average time Puppet Server spends waiting to reserve an instance from the JRuby pool, calculated by dividing the total duration in milliseconds of requested-instances by the requested-count value.</td>
</tr>
<tr>
<td>borrow-count</td>
<td>The total number of JRuby instances that have been used.</td>
</tr>
<tr>
<td>borrow-retry-count</td>
<td>The total number of times that a borrow attempt failed and was retried, such as when the JRuby pool is flushed while a borrow attempt is pending.</td>
</tr>
<tr>
<td>borrow-timeout-count</td>
<td>The number of requests that were not served because they timed out while waiting for a JRuby instance.</td>
</tr>
<tr>
<td>borrowed-instances</td>
<td>A list of the JRuby instances currently in use, each reporting:</td>
</tr>
<tr>
<td></td>
<td>• duration-millis: The length of time that the instance has been running.</td>
</tr>
<tr>
<td></td>
<td>• reason/request: A hash of details about the request being served.</td>
</tr>
<tr>
<td></td>
<td>• request-method: The HTTP request method, such as POST, GET, PUT, or DELETE.</td>
</tr>
<tr>
<td></td>
<td>• route-id: The route being served. For routing metrics, see the HTTP metrics endpoint.</td>
</tr>
<tr>
<td></td>
<td>• uri: The request’s full URI.</td>
</tr>
<tr>
<td></td>
<td>• time: The time (in milliseconds since the Unix epoch) when the JRuby instance was borrowed.</td>
</tr>
<tr>
<td>num-free-jrubies</td>
<td>The number of JRuby instances in the pool that are ready to be used.</td>
</tr>
<tr>
<td>num-jrubies</td>
<td>The total number of JRuby instances.</td>
</tr>
<tr>
<td>num-pool-locks</td>
<td>The total number of times the JRuby pools have been locked.</td>
</tr>
<tr>
<td>requested-count</td>
<td>The number of JRuby instances borrowed, waiting, or that have timed out.</td>
</tr>
</tbody>
</table>
**Key**

- **requested-instances**
  - A list of the requests waiting to be served, each reporting:
    - `duration-millis`: The length of time the request has waited.
    - `reason/request`: A hash of details about the waiting request.
      - `request-method`: The HTTP request method, such as POST, GET, PUT, or DELETE.
      - `route-id`: The route being served. For routing metrics, see the HTTP metrics endpoint.
      - `uri`: The request’s full URI.
    - `time`: The time (in milliseconds since the Unix epoch) when Puppet Server received the request.

- **return-count**
  - The total number of JRuby instances that have been used.

      }
    }
  }
}
```

© 2020 Puppet, Inc.
GET /status/v1/services/pe-master

The /status/v1/services/pe-master endpoint returns JSON containing information about the routes that agents use to connect to this server.

You must query it at port 8140 and append the level=debug URL parameter.

Query parameters

No parameters are supported. Defaults to using the critical status level.

Response codes

The server uses the following response codes:

- 200 if and only if all services report a status of running
- 503 if any service's status is unknown or error

Response keys

The response's experimental/http-metrics section contains a list of routes, each containing the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate</td>
<td>The total time Puppet Server spent processing requests for this route.</td>
</tr>
<tr>
<td>count</td>
<td>The total number of requests Puppet Server processed for this route.</td>
</tr>
<tr>
<td>mean</td>
<td>The average time Puppet Server spent on each request for this route, calculated by dividing the aggregate value by the count.</td>
</tr>
<tr>
<td>route-id</td>
<td>The route being served. The request returns a route with the special route-id of &quot;total&quot;, which represents the aggregate data for all requests along all routes.</td>
</tr>
</tbody>
</table>

Routes for newer versions of Puppet Enterprise and newer agents are prefixed with puppet-v3, while Puppet Enterprise 3 agents' routes are not. For example, a PE 2017.3 route-id might be puppet-v3-report-/*/, while the equivalent PE 3 agent's route-id is :environment-report-/*.
For example:

```
"pe-master": {
    (...),
    "status": {
        "experimental": {
            "http-metrics": [
                {
                    "aggregate": 70668,
                    "count": 234,
                    "mean": 302,
                    "route-id": "total"
                },
                {
                    "aggregate": 28613,
                    "count": 13,
                    "mean": 2201,
                    "route-id": "puppet-v3-catalog-/*/"
                }
            ]
        }
    }
}
```

**GET /status/v1/services/pe-puppet-profiler**

The `/status/v1/services/pe-puppet-profiler` endpoint returns JSON containing statistics about catalog compilation. You can use this data to discover which functions or resources are consuming the most resources or are most frequently used.

You must query it at port 8140 and append the `level=debug` URL parameter.

The Puppet Server profiler is enabled by default, but if it has been disabled, this endpoint's metrics are not available. Instead, the endpoint returns the same keys returned by a standard status endpoint request and an empty `status` key.

**Query parameters**

No parameters are supported. Defaults to using the `critical` status level.

**Response codes**

The server uses the following response codes:

- 200 if and only if all services report a status of `running`
- 503 if any service's status is `unknown` or `error`

**Response keys**

If the profiler is enabled, the response returns two subsections in the `experimental` section:

- `experimental/function-metrics`, containing statistics about functions evaluated by Puppet Server when compiling catalogs.
- `experimental/resource-metrics`, containing statistics about resources declared in manifests compiled by Puppet Server.

Each function measured in the `function-metrics` section also has a `function` key containing the function's name, and each resource measured in the `resource-metrics` section has a `resource` key containing the resource's name.

The two sections otherwise share these keys:
<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate</td>
<td>The total time spent handling this function call or resource during catalog compilation.</td>
</tr>
<tr>
<td>count</td>
<td>The number of times Puppet Server has called the function or instantiated the resource during catalog compilation.</td>
</tr>
<tr>
<td>mean</td>
<td>The average time spent handling this function call or resource during catalog compilation, calculated by dividing the aggregate value by the count.</td>
</tr>
</tbody>
</table>

For example:

```
"pe-puppet-profiler": {
  {...},
  "status": {
    "experimental": {
      "function-metrics": [
        {
          "aggregate": 1628,
          "count": 407,
          "function": "include",
          "mean": 4
        },
        {...},
      ],
      "resource-metrics": [
        {
          "aggregate": 3535,
          "count": 5,
          "mean": 707,
          "resource": "Class[Puppet_enterprise::Profile::Console]"
        },
        {...},
      ]
    }
  }
}
```

The metrics API

Puppet Enterprise includes an optional, enabled-by-default web endpoint for Java Management Extension (JMX) metrics, namely managed beans (MBeans).

These endpoints include:

- GET /metrics/v1/mbeans
- POST /metrics/v1/mbeans
- GET /metrics/v1/mbeans/<name>

Note: These API endpoints are a tech preview. The metrics described here are returned only when passing the level=debug URL parameter, and the structure of the returned data might change in future versions. To disable this endpoint, set puppet_enterprise::master::puppetserver::metrics_webservice_enabled: false in Hiera.
GET /metrics/v1/mbeans
The GET /metrics/v1/mbeans endpoint lists available MBeans.

Response keys
- The key is the name of a valid MBean.
- The value is a URI to use when requesting that MBean's attributes.

POST /metrics/v1/mbeans
The POST /metrics/v1/mbeans endpoint retrieves requested MBean metrics.

Query parameters
The query doesn't require any parameters, but the request body must contain a JSON object whose values are metric names, or a JSON array of metric names, or a JSON string containing a single metric's name.

For a list of metric names, make a GET request to /metrics/v1/mbeans.

Response keys
The response format, though always JSON, depends on the request format:
- Requests with a JSON object return a JSON object where the values of the original object are transformed into the MBeans' attributes for the metric names.
- Requests with a JSON array return a JSON array where the items of the original array are transformed into the MBeans' attributes for the metric names.
- Requests with a JSON string return the a JSON object of the Mbean's attributes for the given metric name.

GET /metrics/v1/mbeans/<name>
The GET /metrics/v1/mbeans/<name> endpoint reports on a single metric.

Query parameters
The query doesn't require any parameters, but the endpoint itself must correspond to one of the metrics returned by a GET request to /metrics/v1/mbeans.

Response keys
The endpoint's responses contain a JSON object mapping strings to values. The keys and values returned in the response vary based on the specified metric.

For example:
Use curl from localhost to request data on MBean memory usage:

Bash

```
curl 'http://localhost:8080/metrics/v1/mbeans/java.lang:type=Memory'
```

The response contains a JSON object representing the data:

```
{
  "ObjectPendingFinalizationCount" : 0,
  "HeapMemoryUsage" : {
    "committed" : 807403520,
    "init" : 268435456,
    "max" : 3817865216,
    "used" : 129257096
  },
  "NonHeapMemoryUsage" : {
    "committed" : 85590016,
```
Managing nodes

Common node management tasks include adding and removing nodes from your deployment, grouping and classifying nodes, and running Puppet on nodes. You can also deploy code to nodes using an environment-based testing workflow or the roles and profiles method.

- **Adding and removing agent nodes** on page 288
  After you install a Puppet agent on a node, accept its certificate signing request and begin managing it with Puppet Enterprise (PE). Or remove nodes that you no longer need.
- **Adding and removing agentless nodes** on page 290
  Using the inventory, you can manage nodes, including devices such as network switches or firewalls, without installing the Puppet agent on them. The inventory stores node and device information securely.
• **How nodes are counted** on page 293
Your *node count* is the number of nodes in your inventory. Your license limits you to a certain number of active nodes before you hit your *bursting limit*. If you hit your bursting limit on four days during a month, you must purchase a license for more nodes or remove some nodes from your inventory.

• **Running Puppet on nodes** on page 294
Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

• **Grouping and classifying nodes** on page 296
Configure nodes by assigning classes, parameters, and variables to them. This is called *classification*.

• **Making changes to node groups** on page 303
You can edit or remove node groups, remove nodes or classes from node groups, and edit or remove parameters and variables.

• **Environment-based testing** on page 304
An environment-based testing workflow is an effective approach for testing new code before pushing it to production.

• **Preconfigured node groups** on page 305
Puppet Enterprise includes preconfigured node groups that are used to manage your configuration.

• **Managing Windows nodes** on page 308
Learn how to use PE to configure and manage essential parts of your infrastructure.

• **Designing system configs: roles and profiles** on page 333
Your typical goal with Puppet is to build complete system configurations, which manage all of the software, services, and configuration that you care about on a given system. The roles and profiles method can help keep complexity under control and make your code more reusable, reconfigurable, and refactorable.

• **Node classifier API v1** on page 358
These are the endpoints for the node classifier v1 API.

• **Node classifier API v2** on page 408
These are the endpoints for the node classifier v2 API.

• **Node inventory API** on page 411
These are the endpoints for the node inventory v1 API.

---

**Adding and removing agent nodes**

After you install a Puppet agent on a node, accept its certificate signing request and begin managing it with Puppet Enterprise (PE). Or remove nodes that you no longer need.

**Managing certificate signing requests**

When you install a Puppet agent on a node, the agent automatically submits a certificate signing request (CSR) to the master. You must accept this request to bring before the node under PE management can be added your deployment. This allows Puppet to run on the node and enforce your configuration, which in turn adds node information to PuppetDB and makes the node available throughout the console.

You can approve certificate requests from the PE console or the command line. If DNS altnames are set up for agent nodes, you must approve the CSRs on use the command line interface.

**Note:** Specific user permissions are required to manage certificate requests:

• To accept or reject CSRs in the console or on the command line, you need the permission **Certificate requests: Accept and reject**.

• To manage certificate requests in the console, you also need the permission **Console: View**.

**Related information**

*Installing agents* on page 106
You can install Puppet Enterprise agents on *nix, Windows, and macOS.

**Managing certificate signing requests in the console**
A certificate signing request appears in the console on the **Unsigned certs** page after you add an agent node to inventory. Accept or reject submitted requests individually or in a batch.

- To manage requests individually, click **Accept** or **Reject**.
- To manage the entire list of requests, click **Accept All** or **Reject All**. Nodes are processed in batches. If you close the browser window or navigate to another website while processing is in progress, only the current batch is processed.

After you accept the certificate signing request, the node appears in the console after the next Puppet run. To make a node available immediately after you approve the request, run Puppet on demand.

**Related information**
Related information

**Running Puppet on demand** on page 441
The orchestrator gives you the ability to set up jobs in the console or on the command line to trigger on-demand Puppet runs.

**Managing certificate signing requests on the command line**
You can view, approve, and reject node requests using the command line.

To view pending node requests on the command line:

```
$ sudo puppetserver ca list
```

To sign a pending request:

```
$ sudo puppetserver ca sign --certname <NAME>
```

**Note:** You can use the Puppet Server CA CLI to sign certificates with altnames or auth extensions by default.

**Remove agent nodes**
If you no longer wish to manage an agent node, you can remove it and make its license available for another node.

Removing a node:

- Deactivates the node in PuppetDB.
- Deletes the Puppet master’s information cache for the node.
- Makes the license available for another node.
- Makes the hostname available for another node.

**Note:** Removing a node doesn't uninstall the agent from the node.

1. On the agent node, stop the agent service.
   - Agent versions 4.0 or later: `service puppet stop`
   - Agent versions earlier than 4.0: `service pe-puppet stop`
   **Note:** To see which version of Puppet is installed on a node, run `puppet --version`.

2. On the master, purge the node: `puppet node purge <CERTNAME>`

   The node’s certificate is revoked, the certificate revocation list (CRL) is updated, and the node is deactivated in PuppetDB and removed from the console. The license is now available for another node. The node can't check in or re-register with PuppetDB on the next Puppet run.

3. If you have compilers, run Puppet on them: `puppet agent -t`

   The updated CRL is managed by Puppet and distributed to compilers.

4. Optional: If the node you’re removing was pinned to any node groups, you must manually unpin it from individual node groups or from all node groups using the `unpin-from-all` command endpoint.
Related information

Uninstall infrastructure nodes on page 136

The puppet-enterprise-uninstaller script is installed on the master. In order to uninstall, you must run the uninstaller on each infrastructure node.

POST /v1/commands/unpin-from-all on page 392

Use the /v1/commands/unpin-from-all to unpin specified nodes from all groups they’re pinned to. Nodes that are dynamically classified using rules aren’t affected.

Uninstall *nix agents

The *nix agent package includes an uninstall script, which you can use when you’re ready to retire a node.

1. On the agent node, run the uninstall script: run /opt/puppetlabs/bin/puppet-enterprise-uninstaller

2. Follow prompts to uninstall.

3. (Optional) If you plan to reinstall on the node at a later date, remove the agent certificate for the agent from the master: puppetserver ca clean <AGENT CERT NAME>

Uninstall Windows agents

To uninstall the agent from a Windows node, use the Windows Add or Remove Programs interface, or uninstall from the command line.

Uninstalling the agent removes the Puppet program directory, the agent service, and all related registry keys. The data directory remains intact, including all SSL keys. To completely remove Puppet from the system, manually delete the data directory.

1. Use the Windows Add or Remove Programs interface to remove the agent.

   Alternatively, you can uninstall from the command line if you have the original .msi file or know the product code of the installed MSI, for example: msiexec /qn /norestart /x [puppet.msi|<PRODUCT_CODE>]

2. (Optional) If you plan to reinstall on the node at a later date, remove the agent certificate for the agent from the master: puppetserver ca clean <AGENT CERT NAME>

Adding and removing agentless nodes

Using the inventory, you can manage nodes, including devices such as network switches or firewalls, without installing the Puppet agent on them. The inventory stores node and device information securely.

The inventory connects to agentless nodes through SSH or WinRM remote connections. The inventory uses transport definitions from installed device modules to connect to devices that can’t have an agent installed on them.

After you add credentials to the inventory, authorized users can run tasks on these nodes and devices without re-entering credentials. On the Tasks page, these nodes and devices appear in the same list of targets as those that have agents installed.

Add agentless nodes to the inventory

Add nodes over SSH or WinRM that will not or cannot have the Puppet agent installed to the inventory so you can run tasks on them.

Before you begin

Add classes to the PE Master node group for each agent platform used in your environment. For example, pe_repo::platform::el_7_x86_64.

Make sure you have the permission Nodes: Add and delete connection information from inventory service.

1. In the console, on the Nodes page, click Add nodes.

2. Click Connect over SSH or WinRM.
3. Select a transport method.
   • SSH for *nix targets
   • WinRM for Windows targets

4. Enter target host names and the credentials required to access them. If you use an SSH key, include begin and end tags.

5. Optional: Select additional target options. For example, to add a target port number, select Target Port from the drop-down list, enter the number, and click Add. For details, see Transport configuration options on page 291.

6. Click Add nodes.

After the nodes have been added to the inventory, they are added to PuppetDB, and you can view them from the Nodes page. Nodes in the inventory can be added to an inventory node list when you set up a job to run tasks. To review each inventory node's connection options, or to remove the node from inventory, go to the Connections tab on the node's details page.

Transport configuration options

A list of transport configuration options for SSH and WinRM transports.

Target options for SSH transport

**Add devices to the inventory**

If you have installed modules for device transports in your production environment, you can add connections to those devices to your inventory. This lets you manage network devices such as switches and firewalls, and run Puppet and task jobs on them, just like other agentless nodes in your infrastructure.

**Before you begin**

Make sure you have the permission **Nodes: Add and delete connection information from inventory service**.

The connection details differ for each type of device transport, as defined in the module; see the device module's README for details.

**CAUTION:** This initial implementation of network device configuration management is limited in how many device connections it can handle. Managing more than 100 devices can cause performance issues on the master. We plan to gather feedback from this release and improve the scaling and performance capabilities. In the meantime, avoid impacting master performance by limiting the number of network device connections you make to 100.

1. In the console, on the **Nodes** page, click **Add nodes**.
2. Click **Connect network devices**.
3. Select a device type from the list of device transports that you have installed as modules in your production environment.
4. Enter the device certname and other connection details, as defined in the transport module. Mandatory fields are marked with an asterisk. See the module README file if you need more details or examples specific to the transport.
5. Click **Add node**.

After devices have been added to the inventory, they are added to PuppetDB, and you can view them from the **Nodes** page. Devices in the inventory can be added to an inventory node list when you set up a job to run tasks. To review each inventory device's connection options, or to remove the device from inventory, go to the **Connections** tab on the device's node details page.

**Remove agentless nodes and devices from the inventory**

Remove an agentless node or device connection from the inventory from the **Connections** tab on its details page.

**Before you begin**

Make sure you have the permission **Nodes: Add and delete connection information from inventory service**.

1. On the **Status** or **Nodes** page, find the node or device whose connection you want to remove, and click its name to open its details page.
2. Click **Connections**.
3. Click **Remove connection**. The exact name of the link varies depending on the connection type: **Remove SSH Connection**, **Remove WinRM connection**, or similar.
4. Confirm that you want to remove the connection.

When you remove a node or device connection from the inventory, PuppetDB marks it as expired after the standard node time-to-live (**node-ttl**) and then purges the node when it reaches its node-purge time-to-live limit (**node-purge-ttl**) at this point the node no longer appears in the console, and the node's license is available for use.

**Tip:** For more information about **node-ttl** and **node-purge-ttl** settings, see the PE docs for **database settings**.

**Related information**

**Node inventory API** on page 411
These are the endpoints for the node inventory v1 API.

## How nodes are counted

Your **node count** is the number of nodes in your inventory. Your license limits you to a certain number of active nodes before you hit your **bursting limit**. If you hit your bursting limit on four days during a month, you must purchase a license for more nodes or remove some nodes from your inventory.

**Note:** *Node* in this context includes agent nodes, agentless nodes, masters, compilers, nodes running in **noop** mode, and nodes that have been purged but had prior activity within the same calendar month.

### Nodes included in the node count

The following nodes are included in your node count:

- Nodes with a report in PuppetDB during the calendar month.
- Nodes that have executed a Puppet run, task, or plan in the orchestrator, even if they do not have a report during the calendar month.

### Nodes not included in the node count

The following nodes are not included in your node count:

- Nodes that are in the inventory service but are not used with Puppet runs, tasks, or plans.
- Nodes that have been purged and have no reports or activity within the calendar month.

### Reaching the bursting limit

When you go above your node license's count limit, you enter what is called the **bursting limit**. The bursting limit lets you to exceed the number of nodes allowed under your license and enter a new threshold without extra charge. You are allowed to use your bursting limit on four consecutive or non-consecutive days per calendar month. Any higher usage beyond the four days will require you to either purge nodes or buy a license for more nodes.

The amount of time within your bursting limit does not matter for it to be counted as one day. For example, assuming you are licensed to use 1000 nodes and your bursting limit is 2000 nodes:

- If you use 1200 nodes for two hours one day, you have three days left to use your bursting limit that month.
- If you use 1900 nodes for 23 hours one day, you have three days left to use your bursting limit that month.
- If you use 1500 nodes for one hour each day for four days, you must contact your Puppet representative to buy a license for more nodes or purge some of your nodes until the next calendar month.

### When nodes are counted

PE tracks node counts daily from 12:00 midnight UTC to 12:00 midnight UTC.

The same time is used for the calendar month. For example, the month of September would include activity from 12:00 midnight UTC 01 September until 12:00 midnight UTC 01 October. After that point, the bursting limit restarts with a fresh four days in October.

### Viewing your node count

View your daily node count in the console by navigating to the **License** page and scrolling to the **Calendar month usage** section. This section also contains information about your subscription expiration date and license warnings, such as your license being expired or out of compliance.

To see daily node usage information on the command line, use the **Puppet orchestrator API: usage endpoint** on page 570.
Removing nodes

If you have unused nodes cluttering your inventory and are concerned about reaching your limit, read about removing them in Adding and removing agent nodes on page 288 and Adding and removing agentless nodes on page 290.

Related information

Purchasing and installing a license key on page 104
Your license must support the number of nodes that you want to manage with Puppet Enterprise.

Running Puppet on nodes

Puppet automatically attempts to run on each of your nodes every 30 minutes. To trigger a Puppet run outside of the default 30-minute interval, you can manually run Puppet.

In a Puppet run, the master and agent nodes perform the following actions:

1. The agent node sends facts to the master and requests a catalog.
2. The master compiles and returns the agent’s catalog.
3. The agent applies the catalog by checking each resource the catalog describes. If it finds any resources that are not in the desired state, it makes the necessary changes.

Note: Puppet run behavior differs slightly if static catalogs are enabled.

Related information

Static catalogs in Puppet Enterprise on page 180
A catalog is a document that describes the desired state for each resource that Puppet manages on a node. A master typically compiles a catalog from manifests of Puppet code. A static catalog is a specific type of Puppet catalog that includes metadata that specifies the desired state of any file resources containing source attributes pointing to puppet:///// locations on a node.

Running Puppet with the orchestrator

The Puppet orchestrator is a set of interactive tools used to deploy configuration changes when and how you want them. You can use the orchestrator to run Puppet from the console, command line, or API.

You can use the orchestrator to enforce change based on a:

- selection of nodes – from the console or the command line:
  
  puppet job run --nodes <COMMA-SEPARATED LIST OF NODE NAMES>

- PQL nodes query – from the console or the command line, for example:
  
  puppet job run --query 'nodes[certname] { facts {name = "operatingsystem" and value = "Debian" }{}

- application or application instance - from the command line.

If you're putting together your own tools for running Puppet or want to enable CI workflows across your infrastructure, use the orchestrator API.

Related information

Running Puppet on demand from the console on page 441
When you set up a job to run Puppet from the console, the orchestrator creates a job ID to track the job, shows you all nodes included in the job, and runs Puppet on those nodes in the appropriate order. Puppet compiles a new catalog for each node included in the job.

Running Puppet with SSH

Run Puppet with SSH from an agent node.

SSH into the node and run puppet agent --test or puppet agent -t.
Running Puppet from the console

In the console, you can run Puppet from the node detail page for nodes that have an agent connection.

Run options include:

- **No-op** – Simulates changes without actually enforcing a new catalog. Nodes with `noop = true` in their `puppet.conf` files always run in no-op mode.
- **Debug** – Prints all messages available for use in debugging.
- **Trace** – Prints stack traces on some errors.
- **Evaltrace** – Shows a breakdown of the time taken for each step in the run.

When the run completes, the console displays the node’s run status.

**Note:** The Run Puppet button is not available if an agent does not have an active websocket session with the PCP broker, or if the node’s connection method is SSH, WinRM, or a network device transport.

**Related information**

- [Node run statuses](#) on page 249

The Status page displays the run status of each node following the most recent Puppet run. There are 10 possible run statuses.

Activity logging on console Puppet runs

When you initiate a Puppet run from the console, the Activity service logs the activity.

You can view activity on a single node by selecting the node, then clicking the Activity tab.

Alternatively, you can use the Activity Service API to retrieve activity information.

**Related information**

- [Activity service API](#) on page 242

The activity service logs changes to role-based access control (RBAC) entities, such as users, directory groups, and user roles.

Troubleshooting Puppet run failures

Puppet creates a View Report link for most failed runs, which you can use to access events and logs.

This table shows some errors that can occur when you attempt to run Puppet, and suggestions for troubleshooting.

<table>
<thead>
<tr>
<th>Error</th>
<th>Possible Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes could not be applied</td>
<td>Conflicting classes are a common cause. Check the log to get more detail.</td>
</tr>

<tr>
<td>Button is disabled and a run is not allowed.</td>
<td>The user has permission, but the agent is not responding.</td>
</tr>
</tbody>
</table>
Grouping and classifying nodes

Configure nodes by assigning classes, parameters, and variables to them. This is called classification.

The main steps involved in classifying nodes are:

1. Create node groups.
2. Add nodes to groups, either manually or dynamically, with rules.
3. Assign classes to node groups.

Nodes can match the rules of many node groups. They receive classes, class parameters, and variables from all the node groups that they match.

How node group inheritance works

Node groups exist in a hierarchy of parent and child relationships. Nodes inherit classes, class parameters and variables, and rules from all ancestor groups.

- Classes – If an ancestor node group has a class, all descendent node groups also have the class.
- Class parameters and variables – Descendent node groups inherit class parameters and variables from ancestors unless a different value is set for the parameter or variable in the descendent node group.
- Rules – A node group can only match nodes that all of its ancestors also match. Specifying rules in a child node group is a way of narrowing down the nodes in the parent node group to apply classes to a specific subset of nodes.

Because nodes can match multiple node groups from separate hierarchical lineages, it’s possible for two equal node groups to contribute conflicting values for variables and class parameters. Conflicting values cause a Puppet run on an agent to fail.

Tip: In the console, you can see how node groups are related on the Node groups page, which displays a hierarchical view of node groups. From the command line, you can use the group children endpoint to review group lineage.

Related information

GET /v1/group-children/:id on page 397
Use the /v1/group-children/:id endpoint to retrieve a specified group and its descendents.

Best practices for classifying node groups

To organize node groups, start with the high-level functional groups that reflect the business requirements of your organization, and work down to smaller segments within those groups.

For example, if a large portion of your infrastructure consists of web servers, create a node group called web servers and add any classes that need to be applied to all web servers.

Next, identify subsets of web servers that have common characteristics but differ from other subsets. For example, you might have production web servers and development web servers. So, create a dev web child node group under the web servers node group. Nodes that match the dev web node group get all of the classes in the parent node group in addition to the classes assigned to the dev web node group.

Create node groups

You can create node groups to assign either an environment or classification.

- Environment node groups assign environments to nodes, such as test, development, or production.
- Classification node groups assign classification data to nodes, including classes, parameters, and variables.

Create environment node groups

Create custom environment node groups so that you can target deployment of Puppet code.

1. In the console, click Node groups, and click Add group.
2. Specify options for the new node group and then click Add.
   • **Parent name** – Select the top-level environment node group in your hierarchy. If you're using default environment node groups, this might be **Production environment** or **All environments**. Every environment node group you add must be a descendant of the top-level environment node group.
   • **Group name** – Enter a name that describes the role of this environment node group, for example, **Test environment**.
   • **Environment** – Select the environment that you want to assign to nodes that match this node group.
   • **Environment group** – Select this option.

You can now add nodes to your environment node group to control which environment each node belongs to.

**Create classification node groups**
Create classification node groups to assign classification data to nodes.

1. In the console, click Node groups, and click Add group.
2. Specify options for the new node group and then click Add.
   • **Parent name** – Select the name of the classification node group that you want to set as the parent to this node group. Classification node groups inherit classes, parameters, and variables from their parent node group. By default, the parent node group is the **All Nodes** node group.
   • **Group name** – Enter a name that describes the role of this classification node group, for example, **Web Servers**.
   • **Environment** – Specify an environment to limit the classes and parameters available for selection in this node group.

   **Note:** Specifying an environment in a classification node group does not assign an environment to any nodes, as it does in an environment node group.
   • **Environment group** – Do not select this option.

You can now add nodes to your classification node group dynamically or statically.

**Add nodes to a node group**
There are two ways to add nodes to a node group.

• Individually pin nodes to the node group (static)
• Create rules that match node facts (dynamic)

**Statically add nodes to a node group**
If you have a node that needs to be in a node group regardless of the rules specified for that node group, you can pin the node to the node group.

A pinned node remains in the node group until you manually remove it. Adding a pinned node essentially creates the rule `<the certname of your node> = <the certname>`, and includes this rule along with the other fact-based rules.

1. In the console, click Node groups, and then find the node group that you want to pin a node to and select it.
2. On the Rules tab, in the pinned nodes section, enter the certname of the node.
3. Click Pin node, and then commit changes.

**Dynamically add nodes to a node group**
Rules are the most powerful and scalable way to include nodes in a node group. You can create rules in a node group that are used to match node facts.

When nodes match the rules in a node group, they’re classified with all of the classification data (classes, parameters, and variables) for the node group.

When nodes no longer match the rules of a node group, the classification data for that node group no longer applies to the node.

1. In the console, click Classification, and then find the node group that you want to add the rule to and select it.
2. On the **Rules** tab, specify rules for the fact, then click **Add rule**.

3. (Optional) Repeat step 2 as needed to add more rules.

   **Tip:** If the node group includes multiple rules, be sure to specify whether **Nodes must match all rules** or **Nodes can match any rule**.

4. Commit changes.

### Writing node group rules
To dynamically assign nodes to a group, you must specify rules based on node facts. Use this reference to fill out the **Rules** tab for node groups.

<table>
<thead>
<tr>
<th>Option</th>
<th>Definition</th>
</tr>
</thead>
</table>
| Fact   | Specifies the fact used to match nodes.  
Select from the list of known facts, or enter part of a string to view fuzzy matches.  
To use structured or trusted facts, select the initial value from the dropdown list, then type the rest of the fact.  
• To descend into a hash, use dots ("." ) to designate path segments, such as `os.release.major` or `trusted.certname`.  
• To specify an item in an array, surround the numerical index of the item in square brackets, such as `processors.models[0]` or `mountpoints./.options[0]`.  
• To identify path segments that contain dots or UTF-8 characters, surround the segment with single or double quotes, such as `trusted.extensions."1.3.6.1.4.1.34380.1.2.1"`.  
• To use trusted extension short names, append the short name after a second dot, such as `trusted.extensions.pp_role`.  
| **Tip:** Structured and trusted facts don't provide type-ahead suggestions beyond the top-level name key, and the facts aren't verified when entered. After adding a rule for a structured or trusted fact, review the number of matching nodes to verify that the fact was entered correctly. |

© 2020 Puppet, Inc.
<table>
<thead>
<tr>
<th>Option</th>
<th>Definition</th>
</tr>
</thead>
</table>
| **Operator** | Describes the relationship between the fact and value. Operators include:  
  - = — is  
  - != — is not  
  - ~ — matches regex  
  - !~ — does not match regex  
  - > — greater than  
  - >= — greater than or equal to  
  - < — less than  
  - <= — less than or equal to  
  The numeric operators >, >=, <, and <= can be used only with facts that have a numeric value.  
  To match highly specific node facts, use ~ or !~ with a regular expression for **Value**. |
| **Value** | Specifies the value associated with the fact. |

**Using structured and trusted facts for node group rules**

Structured facts group a set of related facts, whereas trusted facts are a specific type of structured fact.

**Structured facts** group a set of related facts in the form of a hash or array. For example, the structured fact `os` includes multiple independent facts about the operating system, including architecture, family, and release. In the console, when you view facts about a node, you can differentiate structured facts because they’re surrounded by curly braces.

**Trusted facts** are a specific type of structured fact where the facts are immutable and extracted from a node’s certificate. Because they can’t be changed or overridden, trusted facts enhance security by verifying a node’s identity before sending sensitive data in its catalog.

You can use structured and trusted facts in the console to dynamically add nodes to groups.

**Note:** If you’re using trusted facts to specify certificate extensions, in order for nodes to match to rules correctly, you must use short names for Puppet registered IDs and numeric IDs for private extensions. Numeric IDs are required for private extensions whether or not you specify a short name in the `custom_trusted_oid_mapping.yaml` file.

**Declare classes**

Classes are the blocks of Puppet code used to configure nodes and assign resources to them.

**Before you begin**

The class that you want to apply must exist in an installed module. You can download modules from the Forge or create your own module.

1. In the console, click **Node groups**, and then find the node group that you want to add the class to and select it.
2. On the **Classes** tab, select the class to add.
   
   The **Add new class** field suggests classes that the master knows about and that are available in the environment set for the node group.
3. Click **Add class** and then commit changes.

**Note:** Classes don’t appear in the class list until they’re retrieved from the master and the environment cache is refreshed. By default, both of these actions occur every three minutes. To override the default refresh period and force the node classifier to retrieve the classes from the master immediately, click the **Refresh** button.
Enable data editing in the console

The ability to edit configuration data in the console is enabled by default in new installations. If you upgrade from an earlier version and didn't previously have configuration data enabled, you must manually enable classifier configuration data, because enabling requires edits to your `hiera.yaml` file.

1. On your master, edit `/etc/puppetlabs/puppet/hiera.yaml` to add:

   ```yaml
   hierarchy:
   - name: "Classifier Configuration Data"
     data_hash: classifier_data
   
   Place any additional hierarchy entries, such as `hiera-yaml` or `hiera-eyaml` under the same hierarchy key, preferably below the `Classifier Configuration Data` entry.

   **Note:** If you enable data editing in the console, add both `Set environment` and `Edit configuration data` to groups that set environment or modify class parameters in order for users to make changes.

2. If your environment is configured for disaster recovery, update `hiera.yaml` on your replica.

Define data used by node groups

The console offers multiple ways to specify data used in your manifests.

- **Configuration data** — Specify values through automatic parameter lookup.
- **Parameters** — Specify resource-style values used by a declared class.
- **Variables** — Specify values to make available in Puppet code as top-scope variables.

Set configuration data

Configuration data set in the console is used for automatic parameter lookup, the same way that Hiera data is used. Console configuration data takes precedence over Hiera data, but you can combine data from both sources to configure nodes.

**Tip:** In most cases, setting configuration data in Hiera is the more scalable and consistent method, but there are some cases where the console is preferable. Use the console to set configuration data if:

- You want to override Hiera data. Data set in the console overrides Hiera data when configured as recommended.
- You want to give someone access to set or change data and they don’t have the skill set to do it in Hiera.
- You simply prefer the console user interface.

1. In the console, click **Node groups**, then find the node group that you want to add configuration data to and select it.

2. On the **Configuration data** tab, specify a **Class** and select a **Parameter** to add.

   You can select from existing classes and parameters in the node group's environment, or you can specify free-form values. Classes aren’t validated, but any class you specify must be present in the node’s catalog at runtime in order for the parameter value to be applied.

   When you select a parameter, the **Value** field is automatically populated with the inherited or default value.

3. Optional: Change the default parameter **Value**.

Related information

**Enable data editing in the console** on page 161

The ability to edit configuration data in the console is enabled by default in new installations. If you upgrade from an earlier version and didn't previously have configuration data enabled, you must manually enable classifier configuration data, because enabling requires edits to your `hiera.yaml` file.

**Set parameters**

Parameters are declared resource-style, which means they can be used to override other data; however, this override capability can introduce class conflicts and declaration errors that cause Puppet runs to fail.

1. In the console, click **Node groups**, and then find the node group that you want to add a parameter to and select it.
2. On the **Classes** tab, select the class you want to modify and the **Parameter** to add.

   The **Parameter** drop-down list shows all of the parameters that are available for that class in the node group’s environment. When you select a parameter, the **Value** field is automatically populated with the inherited or default value.

3. (Optional) Change the default **Value**.

**Set variables**

Variables set in the console become top-scope variables available to all Puppet manifests.

1. In the console, click **Node groups**, and then find the node group that you want to set a variable for and select it.

2. On the **Variables** tab, enter options for the variable:
   - **Key** – Enter the name of the variable.
   - **Value** – Enter the value that you want to assign to the variable.

3. Click **Add variable**, and then commit changes.

**Tips for specifying parameter and variable values**

Parameters and variables can be structured as JSON. If they can't be parsed as JSON, they're treated as strings.

Parameters and variables can be specified using these data types and syntax:

- **Strings** (for example, "centos")
  - Variable-style syntax, which interpolates the result of referencing a fact (for example, "I live at $ipaddress.")
  - Expression-style syntax, which interpolates the result of evaluating the embedded expression (for example, ${$os"release"})

  **Note:** Strings must be double-quoted, because single quotes aren’t valid JSON.

  **Tip:** To enter a value in the console that contains a literal dollar sign, like a password hash — for example, $1$nnkkFwEc$safFMXYaUVfKrDv4FLcm0/ — escape each dollar sign with a backslash to disable interpolation.

- **Booleans** (for example, true or false)
- **Numbers** (for example, 123)
- **Hashes** (for example, 
  -  **Note:** Hashes must use colons rather than hash rockets.
- **Arrays** (for example, [:1", "2.3"])

**Variable-style syntax**

Variable-style syntax uses a dollar sign ($) followed by a Puppet fact name.

Example: "I live at $ipaddress"

Variable-style syntax is interpolated as the value of the fact. For example, $ipaddress resolves to the value of the ipaddress fact.

**Important:** The endpoint variable $pe_node_groups cannot be interpolated when used as a classifier in class variable values.

Indexing cannot be used in variable-style syntax because the indices are treated as part of the string literal. For example, given the following fact: processors => {"count" => 4, "physicalcount" => 1}, if you use variable-style syntax to specify $processors[count], the value of the processors fact is interpolated but it is followed by a literal "[count]". After interpolation, this example becomes ("count" => 4,"physicalcount" => 1)[count].

**Note:** Do not use the :: top-level scope indication because the console is not aware of Puppet variable scope.

© 2020 Puppet, Inc.
Expression-style syntax

Use expression-style syntax when you need to index into a fact (${os[release]}), refer to trusted facts ("My name is ${trusted[certname]}"), or delimit fact names from strings ("My ${os} release").

The following is an example of using expression-style syntax to access the full release number of an operating system:

${os"release"}

Expression-style syntax uses the following elements in order:

• an initial dollar sign and curly brace (${
• a legal Puppet fact name preceded by an optional dollar sign
• any number of index expressions (the quotations around indices are optional but are required if the index string contains spaces or square brackets)
• a closing curly brace (})

Indices in expression-style syntax can be used to access individual fields of structured facts, or to refer to trusted facts. Use strings in an index if you want to access the keys of a hashmap. If you want to access a particular item or character in an array or string based on the order in which it is listed, you can use an integer (zero-indexed).

Examples of legal expression-style interpolation:

• ${os}
•:${os}
• ${os[release]}
• ${os['release']}
• ${os["release"]}
• ${os[2]} (accesses the value of the third (zero-indexed) key-value pair in the os hash)
• ${osrelease} (accesses the value of the third key-value pair in the release hash)

In the console, an index can be only simple string literals or decimal integer literals. An index cannot include variables or operations (such as string concatenation or integer arithmetic).

Examples of illegal expression-style interpolation:

• ${::os}
• {os[release]}
• ${os[0xff]}
• ${os[6/3]}
• ${os[$family + $release]}
• ${os + $release}

Trusted facts

Trusted facts are considered to be keys of a hashmap called trusted. This means that all trusted facts must be interpolated using expression-style syntax. For example, the certname trusted fact would be expressed like this: "My name is ${trusted[certname]}". Any trusted facts that are themselves structured facts can have further index expressions to access individual fields of that trusted fact.

Note: Regular expressions, resource references, and other keywords (such as ‘undef’) are not supported.

View nodes in a node group

To view all nodes that currently match the rules specified for a node group:

1. In the console, click Node groups, and then find the node group that you want to view and select it.
2. Click Matching nodes.
You see the number of nodes that match the node group’s rules, along with a list of the names of matching nodes. This is based on the facts collected during the node's last Puppet run. The matching nodes list is updated as rules are added, deleted, and edited. Nodes must match rules in ancestor node groups as well as the rules of the current node group in order to be considered a matching node.

**Making changes to node groups**

You can edit or remove node groups, remove nodes or classes from node groups, and edit or remove parameters and variables.

**Edit or remove node groups**

You can change the name, description, parent, environment, or environment group setting for node groups, or you can delete node groups that have no children.

1. In the console, click **Node groups**, and select a node group.
2. At the top right of the page, select an option.
   - **Edit node group metadata** — Enables edit mode so you can modify the node group's metadata as needed.
   - **Remove node group** — Removes the node group. You're prompted to confirm the removal.
3. Commit changes.

**Remove nodes from a node group**

To remove dynamically-assigned nodes from a node group, edit or delete the applicable rule. To remove statically-assigned nodes from a node group, unpin them from the group.

**Note:** When a node no longer matches the rules of a node group, it is no longer classified with the classes assigned in that node group. However, the resources that were installed by those classes are not removed from the node. For example, if a node group has the **apache** class that installs the Apache package on matching nodes, the Apache package is not removed from the node even when the node no longer matches the node group rules.

1. In the console, click **Node groups**, and select a node group.
2. On the **Rules** tab, select the option appropriate for the type of node.
   - **Dynamically-assigned nodes** — In the **Fact** table, click **Remove** to remove an individual rule, or click **Remove all rules** to delete all rules for the node group.
   - **Statically-assigned nodes** — In the **Certname** table, click **Unpin** to unpin an individual node, or click **Unpin all pinned nodes** to unpin all nodes from the node group.

   **Tip:** To unpin a node from all groups it’s pinned to, use the **unpin-from-all** command endpoint.
3. Commit changes.

**Related information**

POST /v1/commands/unpin-from-all on page 392

Use the /v1/commands/unpin-from-all to unpin specified nodes from all groups they’re pinned to. Nodes that are dynamically classified using rules aren't affected.

**Remove classes from a node group**

Make changes to your node group by removing classes.

**Note:** If a class appears in a node group list but is crossed out, the class has been deleted from Puppet.

1. In the console, click **Node groups**, and select a node group.
2. On the **Classes** tab, click **Remove this class** to remove an individual class, or click **Remove all classes** to remove all classes from the node group.
3. Commit changes.
Edit or remove parameters
Make changes to your node group by editing or deleting the parameters of a class.

1. In the console, click Node groups, and select a node group.
2. On the Classes tab, select an option for the class and parameter you want to edit.
   - Edit — Enables edit mode so you can modify the parameter as needed.
   - Remove — Removes the parameter.
3. Commit changes.

Edit or remove variables
Make changes to your node group by editing or removing variables.

1. In the console, click Node groups, and select a node group.
2. On the Variables tab, select an option.
   - Edit — Enables edit mode so you can modify the variable as needed.
   - Remove — Removes the variable.
   - Remove all variables — Removes all variables from the node group.
3. Commit changes.

Environment-based testing
An environment-based testing workflow is an effective approach for testing new code before pushing it to production.

Before testing and promoting data using an environment-based workflow, you must have configured:

- A test environment that's a child of the production environment
- Classification node groups that include nodes assigned dynamically or statically

Test and promote a parameter
Test and promote a parameter when using an environment-based testing workflow.

1. Create a classification node group with the test environment that is a child of a classification group that uses the production environment.
2. In the child group, set a test parameter. The test parameter overrides the value set by the parent group using the production environment.
3. If you're satisfied with your test results, manually change the parameter in the parent group.
4. (Optional) Delete the child test group.

Test and promote a class
Test and promote a class when using an environment-based testing workflow.

1. Create a classification node group with the test environment that is a child of a classification group that uses the production environment.
   
The node classifier validates your parameters against the test environment.
2. If you're satisfied with your test results, change the environment for the node group from test to production.

Testing code with canary nodes using alternate environments
Puppet Enterprise allows you to centrally manage which nodes are in which environments.

In most cases the environments are long-lived, such as development, testing, and production, and nodes don't move between these environments after their initial environment has been set.
When an agent node matches the rules specified in environment node groups, the agent is classified in that environment regardless of any environments specified in the agent's own `puppet.conf` file. Agents can't override this server-specified environment. That's the desired behavior in most cases.

A notable exception is when you want to test new Puppet code before deployment, and you have a code promotion workflow based on environments. In this case, you can specify that certain nodes are allowed to use an agent-specified environment. You map the agent-specified environment to a feature branch in your version control system. This override enables you to quickly test the code in your feature branch without permanently changing the environment that the node is in.

To apply an agent-specified environment for more than one run, specify the environment in the node's `puppet.conf` file. Doing this also sets the `agent_specified_environment` fact to `true`. The node will continue to get the agent-specified environment until you remove the environment from its `puppet.conf` file, or change the rules in the testing environment group.

**Preconfigured node groups**

Puppet Enterprise includes preconfigured node groups that are used to manage your configuration.

**All Nodes node group**

This node group is at the top of the hierarchy tree. All other node groups stem from this node group.

- **Classes**
  - No default classes. Avoid adding classes to this node group.

- **Matching nodes**
  - All nodes.

- **Notes**
  - You can't modify the preconfigured rule that matches all nodes.

**Infrastructure node groups**

Infrastructure node groups are used to manage PE.

**Important:** Don't make changes to infrastructure node groups other than pinning new nodes for documented functions, like creating compilers. If you want to add custom classifications to infrastructure nodes, create new child groups and apply classification there.

**PE Infrastructure node group**

This node group is the parent to all other infrastructure node groups.

The **PE Infrastructure** node group contains data such as the hostnames and ports of various services and database info (except for passwords).

It's very important to correctly configure the `puppet_enterprise` class in this node group. The parameters set in this class affect the behavior of all other preconfigured node groups that use classes starting with `puppet_enterprise::profile`. Incorrect configuration of this class could potentially cause a service outage.

**CAUTION:** Never remove the **PE Infrastructure** node group. Removing the **PE Infrastructure** node group disrupts communication between all of your **PE Infrastructure** nodes.

- **Classes**
  - `puppet_enterprise` — sets the default parameters for child node groups

- **Matching nodes**
  - Nodes are not pinned to this node group. The **PE Infrastructure** node group is the parent to other infrastructure node groups, such as **PE Master**, and is used only to set classification that all child node groups inherit. Never pin nodes directly to this node group.
These are the parameters for the `puppet_enterprise` class, where `<YOUR HOST>` is your master certname. You can find the certname with `puppet config print certname`.

<table>
<thead>
<tr>

<td>&quot;&lt;YOUR HOST&gt;&quot;</td>
</tr>
</tbody>
</table>

**PE Certificate Authority node group**

This node group is used to manage the certificate authority.

**Classes**

- `puppet_enterprise::profile::certificate_authority` — manages the certificate authority on the first master node

**Matching nodes**

- On a new install, the master is pinned to this node group.

**Notes**

- Don’t add additional nodes to this node group.

**PE Master node group**

This node group is used to manage the Puppet master.

**Classes**

- `puppet-enterprise::profile::master` — manages the Puppet master service

**Matching nodes**

- On a new install, the master is pinned to this node group.

**PE Compiler node group**

This node group is a subset of the **PE Master** node group used to manage compilers running the PuppetDB service.
Classes

- puppet_enterprise::profile::master — manages the Puppet master service
- puppet_enterprise::profile::puppetdb — manages the PuppetDB service

Matching nodes

Compilers running the PuppetDB service are automatically added to this node group.

Notes

Don't add additional nodes to this node group.

**PE Orchestrator node group**

This node group is used to manage the application orchestration service.

Classes

- puppet_enterprise::profile::orchestrator — manages the application orchestration service

Matching nodes

On a new install, the master is pinned to this node group.

Notes

Don't add additional nodes to this node group.

**PE PuppetDB node group**

This node group is used to manage nodes running the PuppetDB service. If the node is also serving as a compiler, it's instead classified in the **PE Compiler** node group.

Classes

- puppet_enterprise::profile::puppetdb — manages the PuppetDB service

Matching nodes

PuppetDB nodes that aren't functioning as compilers are pinned to this node group.

Notes

Don't add additional nodes to this node group.

**PE Console node group**

This node group is used to manage the console.

Classes

- puppet_enterprise::profile::console — manages the console, node classifier, and RBAC
- puppet_enterprise::license — manages the PE license file for the status indicator

Matching nodes

On a new install, the console server node is pinned to this node group.

Notes

Don't add additional nodes to this node group.

**PE Agent node group**

This node group is used to manage the configuration of agents.

Classes

- puppet_enterprise::profile::agent — manages your agent configuration

Matching nodes

All managed nodes are pinned to this node group by default.
PE Infrastructure Agent node group
This node group is a subset of the PE Agent node group used to manage infrastructure-specific overrides.

Classes
puppet_enterprise::profile::agent — manages your agent configuration

Matching nodes
All nodes used to run your Puppet infrastructure and managed by the PE installer are pinned to this node group by default, including the master, PuppetDB, console, and compilers.

Notes
You might want to manually pin to this group any additional nodes used to run your infrastructure, such as compiler load balancer nodes. Pinning a compiler load balancer node to this group allows it to receive its catalog from the master, rather than the compiler, which helps ensure availability.

PE Database node group
This node group is used to manage the PostgreSQL service.

Classes
• puppet_enterprise::profile::database — manages the PE-PostgreSQL service

Matching nodes
The node specified as puppet_enterprise::database_host is pinned to this group. By default, the database host is the PuppetDB server node.

Notes
Don’t add additional nodes to this node group.

Environment node groups
Environment node groups are used only to set environments. They cannot contain any classification.

Preconfigured environment node groups differ depending on your version of PE, and you can customize environment groups as needed for your ecosystem.

Managing Windows nodes
Learn how to use PE to configure and manage essential parts of your infrastructure.

• Using the Windows module pack on page 308
This guide covers creating a managed permission with ACL, creating managed registry keys and values with registry, and installing and creating your own packages with chocolatey.

• Managing Windows configurations on page 324
This page covers the different ways you can use Puppet Enterprise (PE) to manage your Windows configurations, including creating local group and user accounts.

Using the Windows module pack
This guide covers creating a managed permission with ACL, creating managed registry keys and values with registry, and installing and creating your own packages with chocolatey.

Windows module pack
The Windows module pack is a group of modules available on the Forge curated to help you complete common Windows tasks.

The Forge is an online community of Puppet modules submitted by Puppet and community members. The Forge makes it easier for you to manage Puppet and can save you time by using pre-written modules, rather than writing your own. In addition to being rated by the community, modules in the Forge can be Puppet Approved or Puppet
Supported. The major difference is that Approved modules are not available for Puppet Enterprise support services, but are still tested and adhere to a standard for style and quality.

The Windows module pack includes several Windows compatible modules that help you complete common specific tasks. You can find more Windows modules by searching the Forge. While the module pack itself is not supported, the modules by Puppet contained in the pack are individually supported with PE. The rest have been reviewed and recommended by Puppet but are not eligible for commercial support.

The Windows module pack enables you to do the following:

- Read, create, and write registry keys with registry.
- Interact with PowerShell through the Puppet DSL with powershell.
- Manage Windows PowerShell DSC (Desired State Configuration) resources using dsc and dsc_lite.
- Reboot Windows as part of management as necessary through reboot.
- Enforce fine-grained access control permissions using acl.
- Manage Windows Server Update Service configs on client nodes wsus_client.
- Install or remove Windows features with windowsfeature.
- Download files for use during management via download_file.
- Build IIS sites and virtual applications with iis.
- Install packages with chocolatey.
- Manage environment variables with windows_env.

Install the Windows module pack
These steps show you how to install the module pack locally, but you can also install it on the master and pluginsync pushes the module pack to all of your nodes.

1. Open the Puppet command prompt. If you haven’t opened the command line interface before, enter Command Prompt Puppet in your Start Menu, and click Start Command Prompt with Puppet.

2. To list modules that you currently have installed, enter puppet module list in your Command Prompt window. If you’re just getting started, you likely have no modules installed yet.

3. Next, to install the puppetlabs/windows module pack, type puppet module install puppetlabs/windows.

Notice that you get a nice output of everything that’s installed.

C:\>puppet module install puppetlabs/windows
Notice: Preparing to install into
C:\/ProgramData/PuppetLabs/code/environments/production/modules ...
Notice: Downloading from https://forgeapi.puppetlabs.com ...
Notice: Installing -- do not interrupt ...

### puppetlabs-reboot (v1.2.0)
### puppetlabs-registry (v1.1.2)
# ### puppetlabs-stdlib (v4.9.0)
### puppetlabs-wsus_client (v1.0.0)

Manage permissions with acl
The puppetlabs-acl module helps you manage access control lists (ACLs), which provide a way to interact with permissions for the Windows file system. This module enables you to set basic permissions up to very advanced permissions using SIDs (Security Identifiers) with an access mask, inheritance, and propagation strategies. First, start with querying some existing permissions.
View file permissions with ACL

ACL is a custom type and provider, so you can use `puppet resource` to look at existing file and folder permissions.

For some types, you can use the command `puppet resource <TYPE NAME>` to get all instances of that type. However, there could be thousands of ACLs on a Windows system, so it's best to specify the folder you want to review the types in. Here, check `c:\Users` to see what permissions it contains.

In the command prompt, enter `puppet resource acl c:\Users`

```perl
acl { 'c:\Users':
    inherit_parent_permissions => 'false',
    permissions => [
        {identity => 'SYSTEM', rights=> ['full']},
        {identity => 'Administrators', rights => ['full']},
        {identity => 'Users', rights => ['read', 'execute'], affects => 'self_only'},
        {identity => 'Users', rights => ['read', 'execute'], affects => 'children_only'},
        {identity => 'Everyone', rights => ['read', 'execute'], affects => 'self_only'},
        {identity => 'Everyone', rights => ['read', 'execute'], affects => 'children_only'}
    ],
}
```

As you can see, this particular folder does not inherit permissions from its parent folder; instead, it sets its own permissions and determines how child files and folders inherit the permissions set here.

- `{identity => 'SYSTEM', 'rights'=> ['full']}` states that the “SYSTEM” user has full rights to this folder, and by default all children and grandchildren files and folders (as these are the same defaults when creating permissions in Windows).
- `{identity => 'Users', 'rights' => ['read', 'execute'], 'affects' => 'self_only'}` gives read and execute permissions to Users but only on the current directory.
- `{identity => 'Everyone', 'rights' => ['read', 'execute'], 'affects' => 'children_only'}` gives read and execute permissions to everyone, but only on subfolders and files.

**Note:** You might see what appears to be the same permission for a user/group twice (both "Users" and "Everyone" above), where one affects only the folder itself and the other is about children only. They are in fact different permissions.

Create a Puppet managed permission

1. Run this code to create your first Puppet managed permission. Then, save it as `perms.pp`

```perl
file{'c:/tempperms':
    ensure => directory,
}

# By default, the acl creates an implicit relationship to any # file resources it finds that match the location.
ac { 'c:/tempperms':
    permissions => [
        {identity => 'Administrators', rights => ['full']},
        {identity => 'Users', rights => ['read','execute']}
    ],
}
```

2. To validate your manifest, in the command prompt, run `puppet parser validate c:\<FILE PATH>\perms.pp`. If the parser returns nothing, it means validation passed.

© 2020 Puppet, Inc.
3. To apply the manifest, type `puppet apply c:\<FILE PATH>\perms.pp`

   Your output should look similar to:

   Notice: Compiled catalog for win2012r2x64 in environment production in 0.12 seconds
   Notice: /Stage[main]/Main/File[c:/tempperms]/ensure: created
   Notice: /Stage[main]/Main/Acl[c:/tempperms]/permissions: permissions changed [
   ] to [
   { identity => 'BUILTIN\Administrators', rights => ["full"] },
   { identity => 'BUILTIN\Users', rights => ["read", "execute"] }
   ]
   Notice: Applied catalog in 0.05 seconds

4. Review the permissions in your Windows UI. In Windows Explorer, right-click `tempperms` and click Properties. Then, click the Security tab. It should appear similar to the image below.

5. Optional: It might appear that you have more permissions than you were hoping for here. This is because by default Windows inherits parent permissions. In this case, you might not want to do that. Adjust the acl resource to not inherit parent permissions by changing the `perms.pp` file to look like the below by adding `inherit_parent_permissions => false`.

   ```
   acl {'c:/tempperms':
       inherit_parent_permissions => false,
       permissions                => [
         {identity => 'Administrators', rights => ['full']},
         {identity => 'Users', rights => ['read','execute']}
       ],
   }
   ```

6. Save the file, and return the command prompt to run `puppet parser validate c:\<FILE PATH>\perms.pp` again.

7. When it validates, run `puppet apply c:\<FILE PATH>\perms.pp`

   You should get output similar to the following:

   ```
   C:\>puppet apply c:\puppet_code\perms.pp
   Notice: Compiled catalog for win2012r2x64 in environment production in 0.08 seconds
   Notice: /Stage[main]/Main/Acl[c:/tempperms]/inherit_parent_permissions:
   inherit_parent_permissions changed 'true' to 'false'
   Notice: Applied catalog in 0.02 seconds
   ```
8. To check the permissions again, enter `icacls c:\tempperms` in the command prompt. The command, `icacls`, is specifically for displaying and modifying ACLs. The output should be similar to the following:

```
C:\>icacls c:\tempperms
    c:\tempperms BUILTIN\Administrators:(OI)(CI)(F)
    BUILTIN\Users:(OI)(CI)(RX)
    NT AUTHORITY\SYSTEM:(OI)(CI)(F)
    BUILTIN\Users:(CI)(AD)
    CREATOR OWNER:(OI)(CI)(IO)(F)
Successfully processed 1 files; Failed processing 0 files
```

The output shows each permission, followed by a list of specific rights in parentheses. This output shows there are more permissions than you specified in `perms.pp`. Puppet manages permissions next to unmanaged or existing permissions. In the case of removing inheritance, by default Windows copies those existing inherited permissions (or Access Control Entries, ACEs) over to the existing ACL so you have some more permissions that you might not want.

9. Remove the extra permissions, so that only the permissions you’ve specified are on the folder. To do this, in your `perms.pp` set `purge => true` as follows:

```puppet
acl {'c:/tempperms':
    inherit_parent_permissions => false,
    purge                      => true,
    permissions                => [
        {identity => 'Administrators', rights => ['full']},
        {identity => 'Users', rights => ['read','execute']}],
}
```

10. Run the parser command as you have before. If it still returns no errors, then you can apply the change.

11. To apply the change, run `puppet apply c:\<FILE PATH>\perms.pp`. The output should be similar to below:

```
C:\>puppet apply c:\puppet_code\perms.pp
Notice: Compiled catalog for win2012r2x64 in environment production in 0.08 seconds
Notice: /Stage[main]/Main/Acl[c:/tempperms]/permissions: permissions changed [ ] to [ ]
Notice: Applied catalog in 0.05 seconds
```

Puppet outputs a notice as it is removing each of the permissions.

12. Take a look at the output of `icacls` again with `icacls c:\tempperms`

```
c:\>icacls c:\tempperms
    c:\tempperms BUILTIN\Administrators:(OI)(CI)(F)
    BUILTIN\Users:(OI)(CI)(RX)
Successfully processed 1 files; Failed processing 0 files
```
Now the permissions have been set up for this directory. You can get into more advanced permission scenarios if you read the usage scenarios on this module’s Forge page.

**Create Puppet managed registry keys with registry**
You might eventually need to use the registry to access and set highly available settings, among other things. The puppetlabs-registry module, which is also a Puppet Supported Module enables you to set both registry keys and values.

**View registry keys and values with puppet resource**
puppetlabs-registry is a custom type and provider, so you can use puppet resource to look at existing registry settings.

It is also somewhat limited, like the acl module in that it is restricted to only what is specified.

1. In your command prompt, run:

   ```bash
   puppet resource registry_key 'HKLM\Software\Microsoft\Windows'
   ```

   Not that interesting, but now take a look at a registry value.

2. Enter:

   ```bash
   puppet resource registry_value 'HKLM\SYSTEM\CurrentControlSet\Services\BITS\DisplayName'
   ```

   ```bash
text
   registry_value { 'HKLM\SYSTEM\CurrentControlSet\Services\BITS\DisplayName':
     ensure => 'present',
     data   => ['Background Intelligent Transfer Service'],
     type   => 'string',
   }
   ```

   That’s a bit more interesting than a registry key.

Keys are like file paths (directories) and values are like files that can have data and be of different types.
Create managed keys
Learn how to make managed registry keys, and see Puppet correct configuration drift when you try and alter them in Registry Editor.

1. Create your first Puppet managed registry keys and values:

    registry_key { 'HKLM\Software\zTemporaryPuppet':
        ensure => 'present',
    }

    # By default the registry creates an implicit relationship to any file
    # resources it finds that match the location.
    registry_value {'HKLM\Software\zTemporaryPuppet\StringValue':
        ensure => 'present',
        data   => 'This is a custom value.',
        type   => 'string',
    }

    #forcing a 32-bit registry view; watch where this is created:
    registry_key { '32:HKLM\Software\zTemporaryPuppet':
        ensure => 'present',
    }

    registry_value {'32:HKLM\Software\zTemporaryPuppet\StringValue':
        ensure => 'present',
        data   => 'This is a custom 32-bit value.',
        type   => 'expand',
    }

2. Save the file as registry.pp.
3. Validate the manifest. In the command prompt, run puppet parser validate c:<FILE PATH> registry.pp

   If the parser returns nothing, it means validation passed.
4. Now, apply the manifest by running puppet apply c:<FILE PATH>\registry.pp in the command prompt. Your output should look similar to below.

   Notice: Compiled catalog for win2012r2x64 in environment production in 0.11 seconds
   Notice: /Stage[main]/Main/Registry_key[HKLM\Software\zTemporaryPuppet]/ensure: created
   Notice: /Stage[main]/Main/Registry_value[HKLM\Software\zTemporaryPuppet\StringValue]/ensure: created
   Notice: /Stage[main]/Main/Registry_key[32:HKLM\Software\zTemporaryPuppet]/ensure: created
   Notice: /Stage[main]/Main/Registry_value[32:HKLM\Software\zTemporaryPuppet\StringValue]/ensure: created
   Notice: Applied catalog in 0.03 seconds
5. Next, inspect the registry and see what you have. Press **Start + R**, then type `regedit` and press **Enter**. Once the Registry Editor opens, find your keys under **HKEY_LOCAL_MACHINE**.

Note that the 32-bit keys were created under the 32-bit section of Wow6432Node for Software.

6. Apply the manifest again by running `puppet apply c:\<FILE PATH>\registry.pp`

```
Notice: Compiled catalog for win2012r2x64 in environment production in 0.11 seconds
Notice: Applied catalog in 0.02 seconds
```

Nothing changed, so there is no work for Puppet to do.

7. In Registry Editor, change the data. Select **HKLM\Software\zTemporaryPuppet** and in the right box, double-click **StringValue**. Edit the value data, and click **OK**.

```
This time, changes have been made, so running `puppet apply c:\path\to\registry.pp` results in a different output.

```
Notice: Compiled catalog for win2012r2x64 in environment production in 0.11 seconds
Notice: /Stage[main]/Main/Registry_value[HKLM\Software\zTemporaryPuppet \StringValue]/data: data changed 'This is a custom value. Edited' to 'This is a custom value.'
Notice: Applied catalog in 0.03 seconds
```

Puppet automatically corrects the configuration drift.

8. Next, clean up and remove the keys and values. Make your `registry.pp` file look like the below:

```puppet
registry_key { 'HKLM\Software\zTemporaryPuppet':
  ensure => absent,
}

#forcing a 32 bit registry view, watch where this is created
registry_key { '32:HKLM\Software\zTemporaryPuppet':
  ensure => absent,
}
```
9. Validate it with `puppet parser validate c:\path\to\registry.pp` and apply it again with `puppet apply c:\path\to\registry.pp`

    Notice: Compiled catalog for win2012r2x64 in environment production in 0.06 seconds
    Notice: /Stage[main]/Main/Registry_key[HKEY_LOCAL_MACHINE\SOFTWARE\zTemporaryPuppet]/
        ensure: removed
    Notice: /Stage[main]/Main/Registry_key[32:HKEY_LOCAL_MACHINE\Software\zTemporaryPuppet]/
        ensure: removed
    Notice: Applied catalog in 0.02 seconds

    Refresh the view in your Registry Editor. The values are gone.

Example

Here’s a real world example that disables error reporting:

```ruby
class puppetconf::disable_error_reporting {
    registry_value { 'HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting\ForceQueue':
        type => dword,
        data => '1',
    }

    registry_value { 'HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting\DontShowUI':
        type => dword,
        data => '1',
    }

    registry_value { 'HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting\DontSendAdditionalData':
        type => dword,
        data => '1',
    }

    registry_key { 'HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting\Consent':
        ensure => present,
    }

    registry_value { 'HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting\Consent\DefaultConsent':
        type => dword,
        data => '2',
    }
}
```

Create, install and repackage packages with the chocolatey module

Chocolatey is a package manager for Windows that is similar in design and execution to package managers on non-Windows systems. The chocolatey module is a Puppet Approved Module, so it’s not eligible for Puppet Enterprise support services. The module has the capability to install and configure Chocolatey itself, and then manage software on Windows with Chocolatey packages.

© 2020 Puppet, Inc.
**View existing packages**

Chocolatey has a custom provider for the package resource type, so you can use `puppet resource` to view existing packages.

In the command prompt, run `puppet resource package --param provider | more`

The additional provider parameter in this command outputs all types of installed packages that are detected by multiple providers.

**Install Chocolatey**

These steps are to install Chocolatey (choco.exe) itself. You use the module to ensure Chocolatey is installed.

1. Create a new manifest in the chocolatey module called `chocolatey.pp` with the following contents:

   ```
   include chocolatey
   ```

2. Validate the manifest by running `puppet parser validate c:\<FILE PATH>\chocolatey.pp` in the command prompt. If the parser returns nothing, it means validation passed.

3. Apply the manifest by running `puppet apply c:\<FILE PATH>\chocolatey.pp`

   Your output should look similar to below:

   Notice: Compiled catalog for win2012r2x64 in environment production in 0.58 seconds
   Notice: /Stage[main]/Chocolatey::Install/Windows_env[chocolatey_PATH_env]/ensure: created
   Notice: /Stage[main]/Chocolatey::Install/Windows_env[chocolatey_ChocolateyInstall_env]/ensure: created
   Exec[install_chocolatey_official]/return: executed successfully
   Notice: /Stage[main]/Chocolatey::Install/Exec[install_chocolatey_official]: Triggered 'refresh' from 2 events
   Notice: Finished catalog run in 13.22 seconds

   In a production scenario, you’re likely to have a Chocolatey.nupkg file somewhere internal. In cases like that, you can use the internal nupkg for Chocolatey installation:

   ```
   class {'chocolatey':
       chocolatey_download_url => 'https://internalurl/to/chocolatey.nupkg',
       use_7zip                => false,
       log_output              => true,
   }
   ```

**Install a package with chocolatey**

Normally, when installing packages you copy them locally first, make any required changes to bring everything they download to an internal location, repackage the package with the edits, and build your own packages to host on your internal package repository (feed). For this exercise, however, you directly install a portable Notepad++ from Chocolatey's community feed. The Notepad++ CommandLine package is portable and shouldn't greatly affect an existing system.

1. Update the manifest `chocolatey.pp` with the following contents:

   ```
   package {'notepadplusplus.commandline':
       ensure   => installed,
       provider => chocolatey,
   }
   ```
2. Validate the manifest by running `puppet parser validate c:\FILE PATH\chocolatey.pp` in the command prompt. If the parser returns nothing, it means validation passed.

3. Now, apply the manifest with `puppet apply c:\FILE PATH\chocolatey.pp`. Your output should look similar to below.

   ```
   Notice: Compiled catalog for win2012r2x64 in environment production in 0.75 seconds
   Notice: /Stage[main]/Main/Package[notepadplusplus.commandline]/ensure: created
   Notice: Applied catalog in 15.51 seconds
   ```

If you want to use this package for a production scenario, you need an internal custom feed. This is simple to set up with the `chocolatey_server` module. You could also use Sonatype Nexus, Artifactory, or a CIFS share if you want to host packages with a non-Windows option, or you can use anything on Windows that exposes a NuGet OData feed (Nuget is the packaging infrastructure that Chocolatey uses). See the How To Host Feed page of the `chocolatey` wiki for more in-depth information. You could also store packages on your master and use a file resource to verify they are in a specific local directory prior to ensuring the packages.

**Example**

The following example ensures that Chocolatey, the Chocolatey Simple Server (an internal Chocolatey package repository), and some packages are installed. It requires the additional `chocolatey/chocolatey_server` module.

In `c:\FILE PATH\packages` you must have packages for Chocolatey, Chocolatey.Server, Roundhouse, Launchy, and Git, as well as any of their dependencies for this to work.

```bash
case $operatingsystem {
  'windows': {
    Package {
      provider   => chocolatey,
      source     => 'C:\packages',
    }
  }
}

# include chocolatey
class {'chocolatey':
  chocolatey_download_url => 'file:///C:/packages/chocolatey.0.9.9.11.nupkg',
  use_7zip => false,
  log_output => true,
}

# This contains the bits to install the custom server.
# include chocolatey_server
class {'chocolatey_server':
  server_package_source => 'C:/packages',
}

case $operatingsystem {
  'windows': {
    Package {
      provider   => chocolatey,
      source     => 'C:\packages',
    }
  }
}

case $operatingsystem {
  'windows': {
    Package {
      provider   => chocolatey,
      source     => 'C:\packages',
    }
  }
}

# include chocolatey
class {'chocolatey':
  chocolatey_download_url => 'file:///C:/packages/chocolatey.0.9.9.11.nupkg',
  use_7zip => false,
  log_output => true,
}

# This contains the bits to install the custom server.
# include chocolatey_server
class {'chocolatey_server':
  server_package_source => 'C:/packages',
}

package {'roundhouse':
  ensure => '0.8.5.0',
}

package {'launchy':
  ensure => installed,
  install_options => ['-override', '-installArgs''', '/VERYSILENT',' '/NORESTART',' '''],
}

package {'git':

© 2020 Puppet, Inc.
Copy an existing package and make it internal (repackaging packages)

To make the existing package local, use these steps.

Chocolatey's community feed has quite a few packages, but they are geared towards community and use the internet for downloading from official distribution sites. However, they are attractive as they have everything necessary to install a piece of software on your machine. Through the repackaging process, by which you take a community package and bring all of the bits internal or embed them into the package, you can completely internalize a package to host on an internal Chocolatey/NuGet repository. This gives you complete control over a package and removes the aforementioned production trust and control issues.

1. Download the Notepad++ package from Chocolatey's community feed by going to the package page and clicking the download link.
2. Rename the downloaded file to end with .zip and unpack the file as a regular archive.
3. Delete the _rels and package folders and the [Content_Types].xml file. These are created during choco pack and should not be included, because they're regenerated (and their existence leads to issues).

4. Open tools\chocolateyInstall.ps1.

```
Install-ChocolateyZipPackage 'notepadplusplus.commandline' 'https://notepad-plus-plus.org/repository/6.x/6.8.7/npp.6.8.7.bin.zip' "$(Split-Path -parent $MyInvocation.MyCommand.Definition)"
```

5. Download the zip file and place it in the tools folder of the package.
6. Next, edit chocolateyInstall.ps1 to point to this embedded file instead of reaching out to the internet (if the size of the file is over 50MB, you might want to put it on a file share somewhere internally for better performance).

```
$toolsDir   = "$(Split-Path -parent $MyInvocation.MyCommand.Definition)"
Install-ChocolateyZipPackage 'notepadplusplus.commandline' "$toolsDir\npp.6.8.7.bin.zip" "$toolsDir"
```

The double quotes allow for string interpolation (meaning variables get interpreted instead of taken literally).
7. Next, open the *.nuspec file to view its contents and make any necessary changes.

```xml
<?xml version="1.0"?>
<package xmlns="http://schemas.microsoft.com/packaging/2010/07/nuspec.xsd">
  <metadata>
    <id>notepadplusplus.commandline</id>
    <version>6.8.7</version>
    <title>Notepad++ (Portable, CommandLine)</title>
    <authors>Don Ho</authors>
    <owners>Rob Reynolds</owners>
    <projectUrl>https://notepad-plus-plus.org/</projectUrl>
    <iconUrl>https://cdn.rawgit.com/ferventcoder/chocolatey-packages/02c21bebe5abb495a56747cbb9b4b5415c933fc0/icons/notepadplusplus.png</iconUrl>
    <requireLicenseAcceptance>false</requireLicenseAcceptance>
    <description>Notepad++ is a free (as in "free speech" and also as in "free beer") source code editor and Notepad replacement that supports several languages. </description>
    <summary>Notepad++ is a free (as in "free speech" and also as in "free beer") source code editor and Notepad replacement that supports several languages. </summary>
    <tags>notepad notepadplusplus notepad-plus-plus</tags>
  </metadata>
</package>
```

Some organizations change the version field to denote that this is an edited internal package, for example changing 6.8.7 to 6.8.7.20151202. For now, this is not necessary.

8. Now you can navigate via the command prompt to the folder with the .nuspec file (from a Windows machine unless you’ve installed Mono and built choco.exe from source) and use choco pack. You can also be more specific and run choco pack <FILE PATH>
otepadplusplus.commandline.nuspec. The output should be similar to below.

```
Attempting to build package from 'notepadplusplus.commandline.nuspec'.
Successfully created package 'notepadplusplus.commandline.6.8.7.nupkg'
```

Normally you test on a system to ensure that the package you just built is good prior to pushing the package (just the *.nupkg) to your internal repository. This can be done by using choco.exe on a test system to install (choco install notepadplusplus.commandline -source %cd% -change %cd% to $pwd in PowerShell.exe) and uninstall (choco uninstall notepadplusplus.commandline). Another method of testing is to run the manifest pointed to a local source folder, which is what you are going to do.

9. Create \c:\packages and copy the resulting package file (notepadplusplus.commandline.6.8.7.nupkg) into it.

This won’t actually install on this system since you just installed the same version from Chocolatey’s community feed. So you need to remove the existing package first. To remove it, edit your chocolatey.pp to set the package to absent.

```puppet
package {'notepadplusplus.commandline':
  ensure   => absent,
  provider => chocolatey,
}
```

10. Validate the manifest with puppet parser validate path\to\chocolatey.pp. Apply the manifest to ensure the change puppet apply c:\path\to\chocolatey.pp.

You can validate that the package has been removed by checking for it in the package install location or by using choco list -lo.

© 2020 Puppet, Inc.
11. Update the manifest (chocolatey.pp) to use the custom package.

```ruby
package {'notepadplusplus.commandline':
  ensure  => latest,
  provider => chocolatey,
  source   => 'c:\packages',
}
```

12. Validate the manifest with the parser and then apply it again. You can see Puppet creating the new install in the output.

```
Notice: Compiled catalog for win2012r2x64 in environment production in 0.79 seconds
Notice: /Stage[main]/Main/Package[notepadplusplus.commandline]/ensure: created
Notice: Applied catalog in 14.78 seconds
```

13. In an earlier step, you added a *.zip file to the package, so that you can inspect it and be sure the custom package was installed. Navigate to C:\ProgramData\chocolatey\lib \notepadplusplus.commandline\tools (if you have a default install location for Chocolatey) and see if you can find the *.zip file.

You can also validate the chocolateyInstall.ps1 by opening and viewing it to see that it is the custom file you changed.

**Create a package with chocolatey**

Creating your own packages is, for some system administrators, surprisingly simple compared to other packaging standards.

Ensure you have at least Chocolatey CLI (choco.exe) version 0.9.9.11 or newer for this next part.

1. From the command prompt, enter choco new -h to see a help menu of what the available options are.
2. Next, use choco new vagrant to create a package named 'vagrant'. The output should be similar to the following:

```
Creating a new package specification at C:\temppackages\vagrant
Generating template to a file
  at 'C:\temppackages\vagrant\vagrant.nuspec'
Generating template to a file
  at 'C:\temppackages\vagrant\tools\chocolateyinstall.ps1'
Generating template to a file
  at 'C:\temppackages\vagrant\tools\chocolateyuninstall.ps1'
Generating template to a file
  at 'C:\temppackages\vagrant\tools\ReadMe.md'
Successfully generated vagrant package specification files
  at 'C:\temppackages\vagrant'
```

It comes with some files already templated for you to fill out (you can also create your own custom templates for later use).
3. Open `vagrant.nuspec`, and edit it to look like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<package xmlns="http://schemas.microsoft.com/packaging/2015/06/nuspec.xsd">
  <metadata>
    <id>vagrant</id>
    <title>Vagrant (Install)</title>
    <version>1.8.4</version>
    <authors>HashiCorp</authors>
    <owners>my company</owners>
    <description>Vagrant - Development environments made easy.</description>
  </metadata>
  <files>
    <file src="tools\**" target="tools" />
  </files>
</package>
```

Unless you are sharing with the world, you don’t need most of what is in the nuspec template file, so only required items are included above. Match the version of the package in this nuspec file to the version of the underlying software as closely as possible. In this example, Vagrant 1.8.4 is being packaged.

4. Open `chocolateyInstall.ps1` and edit it to look like the following:

```powershell
$ErrorActionPreference = 'Stop';

$packageName = 'vagrant'
$toolsDir = "$(Split-Path -parent $MyInvocation.MyCommand.Definition)"
$fileLocation = Join-Path $toolsDir 'vagrant_1.8.4.msi'

$packageArgs = @{
  packageName = $packageName
  fileType = 'msi'
  file = $fileLocation
  silentArgs = '/qn /norestart'
  validExitCodes= @(0, 3010, 1641)
}

Install-ChocolateyInstallPackage @packageArgs
```

**Note:** The above is `Install-ChocolateyINSTALLPackage`, not to be confused with `Install-ChocolateyPackage`. The names are very close to each other, however the latter also downloads software from a URI (URL, ftp, file) which is not necessary for this example.

5. Delete the `ReadMe.md` and `chocolateyUninstall.ps1` files. Download Vagrant and move it to the tools folder of the package.

**Note:** Normally if a package is over 100MB, it is recommended to move the software installer/archive to a share drive and point to it instead. For this example, just bundle it as is.

6. Now pack it up by using `choco pack`. Copy the new `vagrant.1.8.4.nupkg` file to `c:\packages`.

7. Open the manifest, and add the new package you just created. Your `chocolatey.pp` file should look like the below:

```puppet
package {'vagrant':
  ensure => installed,
  provider => chocolatey,
  source => 'c:\packages',
}
```

8. Save the file and make sure to validate with the Puppet parser.
9. Use puppet apply <FILE PATH>\chocolatey.pp to run the manifest.
10. Open Control Panel, Programs and Features and take a look.

![Uninstall or change a program](image)

Vagrant is installed!

**Uninstall packages with Chocolatey**

In addition to installing and creating packages, Chocolatey can also help you uninstall them.

To verify that the choco autoUninstaller feature is turned on, use choco feature to list the features and their current state. If you’re using include chocolatey or class chocolatey to ensure Chocolatey is installed, the configuration is applied automatically (unless you have explicitly disabled it). Starting in Chocolatey version 0.9.10, it is enabled by default.

1. If you see autoUninstaller - [Disabled], you need to enable it. To do this, in the command prompt, run choco feature enable -n autoUninstaller

You should see a similar success message:

_enabled autoUninstaller_

2. To remove Vagrant, edit your chocolatey.pp manifest to ensure => absent. Then save and validate the file.

```puppet
package {'vagrant':
  ensure => absent,
  provider => chocolatey,
  source => 'c:\packages',
}
```

3. Next, run puppet apply <FILE PATH>\chocolatey.pp to apply the manifest.

Notice: Compiled catalog for win2012r2x64 in environment production in 0.75 seconds
Notice: /Stage[main]/Main/Package[vagrant]/ensure: removed
Notice: Applied catalog in 40.85 seconds

You can look in the Control Panel, Programs and Features to see that it’s no longer installed!
Managing Windows configurations

This page covers the different ways you can use Puppet Enterprise (PE) to manage your Windows configurations, including creating local group and user accounts.

Basic tasks and concepts in Windows

This section is meant to help familiarize you with several common tasks used in Puppet Enterprise (PE) with Windows agents, and explain the concepts and reasons behind performing them.

Practice tasks

In other locations in the documentation, these can be found as steps in tasks, but they are not explained as thoroughly.

Write a simple manifest

Puppet manifest files are lists of resources that have a unique title and a set of named attributes that describe the desired state.

Before you begin

You need a text editor, for example Visual Studio Code (VS Code), to create manifest files. Puppet has an extension for VS Code that supports syntax highlighting of the Puppet language. Editors like Notepad++ or Notepad won't highlight Puppet syntax, but can also be used to create manifests.

Manifest files are written in Puppet code, a domain specific language (DSL) that defines the desired state of resources on a system, such as files, users, and packages. Puppet compiles these text-based manifests into catalogs, and uses those to apply configuration changes.

1. Create a file named file.pp and save it in c:\myfiles\

2. With your text editor of choice, add the following text to the file:

```puppet
file { 'c:\Temp\foo.txt':
  ensure   => present,
  content  => 'This is some text in my file'
}
```

Note the following details in this file resource example:

- Puppet uses a basic syntax of type { title: }, where type is the resource type — in this case it's file.
- The resource title (the value before the :) is C:\Temp\foo.txt. The file resource uses the title to determine where to create the file on disk. A resource title must always be unique within a given manifest.
- The ensure parameter is set to present to create the file on disk, if it's not already present. For file type resources, you can also use the value absent, which removes the file from disk if it exists.
- The content parameter is set to This is some text in my file, which writes that value to the file.

Validate your manifest with puppet parser validate

You can validate that a manifest's syntax is correct by using the command puppet parser validate

1. Check your syntax by entering puppet parser validate c:\myfiles\file.pp in the Puppet command prompt. If a manifest has no syntax errors, the tool outputs nothing.

2. To see what output occurs when there is an error, temporarily edit the manifest and remove the : after the resource title. Run puppet parser validate c:\myfiles\file.pp again, and see the following output:

```
Error: Could not parse for environment production: Syntax error at 'ensure' at c:/myfiles/file.pp:2:3
```

Launch the Puppet command prompt

A lot of common interactions with Puppet are done via the command line.

To open the command line interface, enter Command Prompt Puppet in your Start Menu, and click Start Command Prompt with Puppet.

The Puppet command prompt has a few details worth noting:
• Several important batch files live in the current working directory, C:\Program Files\Puppet Labs\Puppet\bin. The most important of these batch files is puppet.bat. Puppet is a Ruby based application, and puppet.bat is a wrapper around executing Puppet code through ruby.exe.

• Running the command prompt with Puppet rather than just the default Windows command prompt ensures that all of the Puppet tooling is in PATH, even if you change to a different directory.

**Simulate a Puppet run with --noop**

Puppet has a switch that you can use to test if manifests make the intended changes. This is referred to as non-enforcement or no-op mode.

To simulate changes, run `puppet apply c:\myfiles\file.pp --noop` in the command prompt:

```
C:\Program Files\Puppet Labs\Puppet\bin>puppet apply c:\myfiles\file.pp --noop
Notice: Compiled catalog for win-User.localdomain in environment production in 0.45 seconds
Notice: /Stage[main]/MainFile[C:\Temp\foo.txt]/ensure: current value absent, should be present (noop)
Notice: Class[Main]: Would have triggered 'refresh' from 1 events
Notice: Stage[main]: Would have triggered 'refresh' from 1 events
Notice: Applied catalog in 0.03 seconds
```

Puppet shows you the changes it *would* make, but does not actually make the changes. It *would* create a new file at C:\Temp\foo.txt, but it hasn't, because you used --noop.

**Enforce the desired state with puppet apply**

When the output of the simulation shows the changes you intend to make, you can start enforcing these changes with the puppet apply command.

Run `puppet apply c:\myfiles\file.pp`.

To see more details about what this command did, you can specify additional options, such as --trace, --debug, or --verbose, which can help you diagnose problematic code. If puppet apply fails, Puppet outputs a full stack trace.

Puppet enforces the resource state you've described in file.pp, in this case guaranteeing that a file (c:\Temp\foo.txt) is present and has the contents *This is some text in my file.*

**Understanding idempotency**

A key feature of Puppet is its *idempotency*: the ability to repeatedly apply a manifest to guarantee a desired resource state on a system, with the same results every time.

If a given resource is already in the desired state, Puppet performs no actions. If a given resource is not in the desired state, Puppet takes whatever action is necessary to put the resource into the desired state. Idempotency enables Puppet to simulate resource changes without performing them, and lets you set up configuration management one time, fixing configuration drift without recreating resources from scratch each time Puppet runs.

To demonstrate how Puppet can be applied repeatedly to get the same results, change the manifest at c:\myfiles\file.pp to the following:

```
file { 'C:\Temp\foo.txt':
  ensure => present,
  content => 'I have changed my file content.'
}
```

Apply the manifest by running `puppet apply c:\myfiles\file.pp`. Open c:\Temp\foo.txt and notice that Puppet changes the file's contents.

Applying the manifest again with `puppet apply c:\myfiles\file.pp` results in no changes to the system, demonstrating that Puppet behaves idempotently.
Many of the samples in Puppet documentation assume that you have this basic understanding of creating and editing manifest files, and applying them with `puppet apply`.

**Additional command line tools**

Once you understand how to write manifests, validate them, and use `puppet apply` to enforce your changes, you’re ready to use commands such as `puppet agent`, `puppet resource`, and `puppet module install`.

**puppet agent**

Like `puppet apply`, the `puppet agent` command line tool applies configuration changes to a system. However, `puppet agent` retrieves compiled catalogs from a Puppet Server, and applies them to the local system. Puppet is installed as a Windows service, and by default tries to contact the master every 30 minutes by running `puppet agent` to retrieve new catalogs and apply them locally.

**puppet resource**

You can run `puppet resource` to query the state of a particular type of resource on the system. For example, to list all of the users on a system, run the command `puppet resource user`.

![Output of puppet resource user command](image)

The computer used for this example has three local user accounts: Administrator, Guest, and vagrant. Note that the output is the same format as a manifest, and you can copy and paste it directly into a manifest.

**puppet module install**

Puppet includes many core resource types, plus you can extend Puppet by installing modules. Modules contain additional resource definitions and the code necessary to modify a system to create, read, modify, or delete those resources. The Puppet Forge contains modules developed by Puppet and community members available for anyone to use.

Puppet synchronizes modules from a master to agent nodes during `puppet agent` runs. Alternatively, you can use the standalone Puppet module tool, included when you install Puppet, to manage, view, and test modules.

Run `puppet module list` to show the list of modules installed on the system.

To install modules, the Puppet module tool uses the syntax `puppet module install NAMESPACE/MODULENAME`. The `NAMESPACE` is registered to a module, and `MODULE` refers to the specific module name. A very common module to install on Windows is `registry`, under the `puppetlabs` namespace. So, to install the `registry` module, run `puppet module install puppetlabs/registry`. © 2020 Puppet, Inc.
Manage Windows services
You can use Puppet to manage Windows services, specifically, to start, stop, enable, disable, list, query, and configure services. This way, you can ensure that certain services are always running or are disabled as necessary.

You write Puppet code to manage services in the manifest. When you apply the manifest, the changes you make to the service are applied.

Note: In addition to using manifests to apply configuration changes, you can query system state using the puppet resource command, which emits code as well as applying changes.

Ensure a Windows service is running
There are often services that you always want running in your infrastructure.

To have Puppet ensure that a service is running, use the following code:

```
service { '<service name>':
   ensure => 'running'
}
```

Example
For example, the following manifest code ensures the Windows Time service is running:

```
service { 'w32time':
   ensure => 'running'
}
```

Stop a Windows service
Some services can impair performance, or might need to be stopped for regular maintenance.

To disable a service, use the code:

```
service { '<service name>':
   ensure => 'stopped',
   enable => 'false'
}
```

Example
For example, this disables the disk defragmentation service, which can negatively impact service performance.

```
service { 'deffragsvc':
   ensure => 'stopped',
   enable => 'false'
}
```

Schedule a recurring operation with Windows Task Scheduler
Regularly scheduled operations, or tasks, are often necessary on Windows to perform routine system maintenance.

Note: If you need to run an ad-hoc task in the PE console or on the command line, see Running tasks in PE on page 460.

If you need to sync files from another system on the network, perform backups to another disk, or execute log or index maintenance on SQL Server, you can use Puppet to schedule and perform regular tasks. The following shows how to regularly delete files.

To delete all files recursively from C:\Windows\Temp at 8 AM each day, create a resource called scheduled_task with these attributes:

```
scheduled_task { 'Purge global temp files':
   ensure => present,
   enabled => true,
   command => 'c:\windows\system32\cmd.exe',
```
arguments => '/c "del c:\windows\temp\*.* /F /S /Q"',
trigger => {
    schedule => daily,
    start_time => '08:00',
}
}

After you set up Puppet to manage this task, the Task Scheduler includes the task you specified:

![Task Scheduler screenshot]

**Example**

In addition to creating a trivial daily task at a specified time, the scheduled task resource supports a number of other more advanced scheduling capabilities, including more fine-tuned scheduling. For example, to change the above task to instead perform a disk clean-up every 2 hours, modify the trigger definition:

```yaml
scheduled_task { 'Purge global temp files every 2 hours':
    ensure => present,
    enabled => true,
    command => 'c:\windows\system32\cmd.exe',
    arguments => '/c "del c:\windows\temp\*.* /F /S /Q"',
    trigger => [{
        day_of_week => ['mon', 'tues', 'wed', 'thurs', 'fri'],
        every => '1',
        minutes_interval => '120',
        minutes_duration => '1440',
        schedule => 'weekly',
        start_time => '07:30',
    },
    user => 'system',
}
```
You can see the corresponding definition reflected in the Task Scheduler GUI:

![Edit Trigger GUI](image)

**Manage Windows users and groups**
Puppet can be used to create local group and user accounts. Local user accounts are often desirable for isolating applications requiring unique permissions.

**Manage administrator accounts**
It is often necessary to standardize the local Windows Administrator password across an entire Windows deployment.

To manage administrator accounts with Puppet, create a user resource with 'Administrator' as the resource title like so:

```puppet
user { 'Administrator':
  ensure => present,
  password => 'yabbadabba'
}
```

**Note:** Securing the password used in the manifest is beyond the scope of this introductory example, but it’s common to use Hiera, a key/value lookup tool for configuration, with eyaml to solve this problem. Not only does this solution provide secure storage for the password value, but it also provides parameterization to support reuse, opening the door to easy password rotation policies across an entire network of Windows machines.
Configure an app to use a different account

You might not always want to use the default user for an application, you can use Puppet to create users for other applications, like ASP.NET.

To configure ASP.NET apps to use accounts other than the default Network Service, create a user and exec resource:

```puppet
user { 'aspnet_banking_app':
  ensure          => present,
  managehome      => true,
  comment         => 'ASP.NET Service account for Banking application',
  password        => 'banking_app_password',
  groups          => ['IIS_IUSRS', 'Users'],
  auth_membership => 'minimum',
  notify          => Exec['regiis_aspnet_banking_app']
}

eexec { 'regiis_aspnet_banking_app':
  path        => 'c:\windows\Microsoft.NET\Framework\v4.0.30319',
  command     => 'aspnet_regiis.exe -ga aspnet_banking_app',
  refreshonly => true
}
```

In this example, the user is created in the appropriate groups, and the ASP.NET IIS registration command is run after the user is created to ensure file permissions are correct.

In the user resource, there are a few important details to note:

- `managehome` is set to create the user's home directory on disk.
auth_membership is set to minimum, meaning that Puppet makes sure the aspnet_banking_app user is a part of the IIS_IUSRS and Users group, but doesn't remove the user from any other groups it might be a part of.

notify is set on the user, and refreshonly is set on the exec. This tells Puppet to run aspnet_regiis.exe only when the aspnet_banking_app is created or changed.

**Manage local groups**

Local user accounts are often desirable for isolating applications requiring unique permissions. It can also be useful to manipulate existing local groups.

To add domain users or groups not present in the Domain Administrators group to the local Administrators group, use this code:

```puppet
group { 'Administrators':
  ensure  => 'present',
  members => ['DOMAIN\User'],
  auth_membership => false
}
```

In this case, auth_membership is set to false to ensure that DOMAIN\User is present in the Administrators group, but that other accounts that might be present in Administrators are not removed.

Note that the groups attribute of user and the members attribute of group might both accept SID values, like the well-known SID for Administrators, S-1-5-32-544.

**Executing PowerShell code**

Some Windows maintenance tasks require the use of Windows Management Instrumentation (WMI), and PowerShell is the most useful way to access WMI methods. Puppet has a special module that can be used to execute arbitrary PowerShell code.

A common Windows maintenance tasks is to disable Windows drive indexing, because it can negatively impact disk performance on servers.

To disable drive indexing:

```powershell
$drive = 'C:'

exec { 'disable-c-indexing':
  provider => powershell,
  command => "\$wmi_volume = Get-WmiObject -Class Win32_Volume -Filter 'DriveLetter="$\{drive\}"'; if (\$wmi_volume.IndexingEnabled -ne \$True) { return }; \$wmi_volume | Set-WmiInstance -Arguments @{IndexingEnabled = \$False}",
  unless => "if ((Get-WmiObject -Class Win32_Volume -Filter 'DriveLetter="$\{drive\}"').IndexingEnabled) { exit 1 }",
}
```

You can see the results in your object editor window:
Using the Windows built-in WBEMTest tool, running this manifest sets `IndexingEnabled` to `FALSE`, which is the desired behavior.

This `exec` sets a few important attributes:

- The provider is configured to use PowerShell (which relies on the module).
- The command contains inline PowerShell, and as such, must be escaped with PowerShell variables preceded with `$` must be escaped as `\$`.
- The `unless` attribute is set to ensure that Puppet behaves idempotently, a key aspect of using Puppet to manage resources. If the resource is already in the desired state, Puppet does not modify the resource state.

**Using templates to better manage Puppet code**

While inline PowerShell is usable as an `exec` resource in your manifest, such code can be difficult to read and maintain, especially when it comes to handling escaping rules.

For executing multi-line scripts, use Puppet templates instead. The following example shows how you can use a template to organize the code for disabling Windows drive indexing.

```bash
$drive = 'C:'

exec { 'disable-c-indexing':
  command   => template('Disable-Indexing.ps1.erb'),
  provider  => powershell,
  unless    => "if ((Get-WmiObject -Class Win32_Volume -Filter 'DriveLetter= \"${drive}\"').IndexingEnabled) { exit 1 }",
}
```
The PowerShell code for Disable-Indexing.ps1.erb becomes:

```powershell
function Disable-Indexing($Drive)
{
    $drive = Get-WmiObject -Class Win32_Volume -Filter "DriveLetter='$Letter'"
    if ($drive.IndexingEnabled -ne $True) { return }
    $drive | Set-WmiInstance -Arguments @{IndexingEnabled=$False} | Out-Null
}

Disable-Indexing -Drive '<%= @driveLetter %>'
```

Designing system configs: roles and profiles

Your typical goal with Puppet is to build complete system configurations, which manage all of the software, services, and configuration that you care about on a given system. The roles and profiles method can help keep complexity under control and make your code more reusable, reconfigurable, and refactorable.

- **The roles and profiles method** on page 333
  The *roles and profiles* method is the most reliable way to build reusable, configurable, and refactorable system configurations.
- **Roles and profiles example** on page 336
  This example demonstrates a complete roles and profiles workflow. Use it to understand the roles and profiles method as a whole. Additional examples show how to design advanced configurations by refactoring this example code to a higher level of complexity.
- **Designing advanced profiles** on page 338
  In this advanced example, we iteratively refactor our basic roles and profiles example to handle real-world concerns. The final result is — with only minor differences — the Jenkins profile we use in production here at Puppet.
- **Designing convenient roles** on page 355
  There are several approaches to building roles, and you must decide which ones are most convenient for you and your team.

The roles and profiles method

The *roles and profiles* method is the most reliable way to build reusable, configurable, and refactorable system configurations.

It's not a straightforward recipe: you must think hard about the nature of your infrastructure and your team. It's also not a final state: expect to refine your configurations over time. Instead, it's an approach to designing your infrastructure's interface — sealing away incidental complexity, surfacing the significant complexity, and making sure your data behaves predictably.

Building configurations without roles and profiles

Without roles and profiles, people typically build system configurations in their node classifier or main manifest, using Hiera to handle tricky inheritance problems. A standard approach is to create a group of similar nodes and assign classes to it, then create child groups with extra classes for nodes that have additional needs. Another common pattern is to put everything in Hiera, using a very large hierarchy that reflects every variation in the infrastructure.

If this works for you, then it works! You might not need roles and profiles. But most people find direct building gets difficult to understand and maintain over time.

Configuring roles and profiles

Roles and profiles are **two extra layers of indirection** between your node classifier and your component modules.

The roles and profiles method separates your code into three levels:

- Component modules — Normal modules that manage one particular technology, for example puppetlabs/apache.
- Profiles — Wrapper classes that use multiple component modules to configure a layered technology stack.
- Roles — Wrapper classes that use multiple profiles to build a complete system configuration.
These extra layers of indirection might seem like they add complexity, but they give you a space to build practical, business-specific interfaces to the configuration you care most about. A better interface makes hierarchical data easier to use, makes system configurations easier to read, and makes refactoring easier.

In short, from top to bottom:

- Your node classifier assigns one role class to a group of nodes. The role manages a whole system configuration, so no other classes are needed. The node classifier does not configure the role in any way.
- That role class declares some profile classes with include, and does nothing else. For example:

```ruby
class role::jenkins::master {
  include profile::base
  include profile::server
  include profile::jenkins::master
}
```

- Each profile configures a layered technology stack, using multiple component modules and the built-in resource types. (In the diagram, profile::jenkins::master uses puppet/jenkins, puppetlabs/apt, a home-built backup module, and some package and file resources.)
- Profiles can take configuration data from the console, Hiera, or Puppet lookup. (In the diagram, three different hierarchy levels contribute data.)
- Classes from component modules are always declared via a profile, and never assigned directly to a node.
  - If a component class has parameters, you specify them in the profile; never use Hiera or Puppet lookup to override component class params.
Rules for profile classes
There are rules for writing profile classes.

- Make sure you can safely include any profile multiple times — don't use resource-like declarations on them.
- Profiles can include other profiles.
- Profiles own all the class parameters for their component classes. If the profile omits one, that means you definitely want the default value; the component class shouldn't use a value from Hiera data. If you need to set a class parameter that was omitted previously, refactor the profile.
- There are three ways a profile can get the information it needs to configure component classes:
  - If your business always uses the same value for a given parameter, hardcode it.
  - If you can't hardcode it, try to compute it based on information you already have.
  - Finally, if you can't compute it, look it up in your data. To reduce lookups, identify cases where multiple parameters can be derived from the answer to a single question.

This is a game of trade-offs. Hardcoded parameters are the easiest to read, and also the least flexible. Putting values in your Hiera data is very flexible, but can be very difficult to read: you might have to look through a lot of files (or run a lot of lookup commands) to see what the profile is actually doing. Using conditional logic to derive a value is a middle-ground. Aim for the most readable option you can get away with.

Rules for role classes
There are rules for writing role classes.

- The only thing roles should do is declare profile classes with include. Don't declare any component classes or normal resources in a role.

  Optionally, roles can use conditional logic to decide which profiles to use.
- Roles should not have any class parameters of their own.
- Roles should not set class parameters for any profiles. (Those are all handled by data lookup.)
- The name of a role should be based on your business’s conversational name for the type of node it manages.

  This means that if you regularly call a machine a "Jenkins master," it makes sense to write a role named role::jenkins::master. But if you call it a "web server," you shouldn't use a name like role::nginx — go with something like role::web instead.

Methods for data lookup
Profiles usually require some amount of configuration, and they must use data lookup to get it.

This profile uses the automatic class parameter lookup to request data.

```yaml
# Example Hiera data
profile::jenkins::jenkins_port: 8000
profile::jenkins::java_dist: jre
profile::jenkins::java_version: '8'

# Example manifest
class profile::jenkins {
    Integer $jenkins_port,
    String  $java_dist,
    String  $java_version
} {
    # ...
}
```

This profile omits the parameters and uses the lookup function:

```ruby
class profile::jenkins {
    $jenkins_port = lookup('profile::jenkins::jenkins_port', {value_type => String, default_value => '9091'})
    $java_dist    = lookup('profile::jenkins::java_dist', {value_type => String, default_value => 'jdk'})
}
```
$java_version = lookup('profile::jenkins::java_version', {value_type => String, default_value => 'latest'})

In general, class parameters are preferable to lookups. They integrate better with tools like Puppet strings, and they’re a reliable and well-known place to look for configuration. But using lookup is a fine approach if you aren’t comfortable with automatic parameter lookup. Some people prefer the full lookup key to be written in the profile, so they can globally grep for it.

Roles and profiles example
This example demonstrates a complete roles and profiles workflow. Use it to understand the roles and profiles method as a whole. Additional examples show how to design advanced configurations by refactoring this example code to a higher level of complexity.

Configure Jenkins master servers with roles and profiles
Jenkins is a continuous integration (CI) application that runs on the JVM. The Jenkins master server provides a web front-end, and also runs CI tasks at scheduled times or in reaction to events.

In this example, we manage the configuration of Jenkins master servers.

Set up your prerequisites
If you're new to using roles and profiles, do some additional setup before writing any new code.

1. Create two modules: one named role, and one named profile.
   If you deploy your code with Code Manager or r10k, put these two modules in your control repository instead of declaring them in your Puppetfile, because Code Manager and r10k reserve the modules directory for their own use.
   a. Make a new directory in the repo named site.
   b. Edit the environment.conf file to add site to the modulepath. (For example: modulepath = site:modules:$basemodulepath).
   c. Put the role and profile modules in the site directory.
2. Make sure Hiera or Puppet lookup is set up and working, with a hierarchy that works well for you.

Choose component modules
For our example, we want to manage Jenkins itself using the puppet/jenkins module.

Jenkins requires Java, and the puppet/jenkins module can manage it automatically. But we want finer control over Java, so we're going to disable that. So, we need a Java module, and puppetlabs/java is a good choice.

That's enough to start with. We can refactor and expand when we have those working.

To learn more about these modules, see puppet/jenkins and puppetlabs/java.

Write a profile
From a Puppet perspective, a profile is just a normal class stored in the profile module.

Make a new class called profile::jenkins::master, located at .../profile/manifests/jenkins/master.pp, and fill it with Puppet code.

```puppet
class profile::jenkins::master (
  String $jenkins_port = '9091',
  String $java_dist    = 'jdk',
  String $java_version = 'latest',
) {

  class { 'jenkins':
    configure_firewall => true,
    install_java     => false,
    port             => $jenkins_port,
  }
}
```

© 2020 Puppet, Inc.
config_hash => {
    'HTTP_PORT' => { 'value' => $jenkins_port },
    'JENKINS_PORT' => { 'value' => $jenkins_port },
},
}
}

class { 'java':
    distribution => $java_dist,
    version      => $java_version,
    before       => Class['jenkins'],
}
}

This is pretty simple, but is already benefiting us: our interface for configuring Jenkins has gone from 30 or so parameters on the Jenkins class (and many more on the Java class) down to three. Notice that we’ve hardcoded the configure_firewall and install_java parameters, and have reused the value of $jenkins_port in three places.

There are rules for writing profile classes.

Methods for data lookup on page 335
Profiles usually require some amount of configuration, and they must use data lookup to get it.

Set data for the profile
Let’s assume the following:

- We use some custom facts:
  - group: The group this node belongs to. (This is usually either a department of our business, or a large-scale function shared by many nodes.)
  - stage: The deployment stage of this node (dev, test, or prod).

- We have a five-layer hierarchy:
  - console_data for data defined in the console.
  - nodes/%{trusted.certname} for per-node overrides.
  - groups/%{facts.group}/%{facts.stage} for setting stage-specific data within a group.
  - groups/%{facts.group} for setting group-specific data.
  - common for global fallback data.

- We have a few one-off Jenkins masters, but most of them belong to the ci group.
- Our quality engineering department wants masters in the ci group to use the Oracle JDK, but one-off machines can just use the platform’s default Java.
- QE also wants their prod masters to listen on port 80.

Set appropriate values in the data, using either Hiera or configuration data in the console.

Tip: In most cases, setting configuration data in Hiera is the more scalable and consistent method, but there are some cases where the console is preferable. Use the console to set configuration data if:

- You want to override Hiera data. Data set in the console overrides Hiera data when configured as recommended.
- You want to give someone access to set or change data and they don’t have the skill set to do it in Hiera.
- You simply prefer the console user interface.

# /etc/puppetlabs/code/environments/production/data/nodes/ci-master01.example.com.yaml
# --Nothing. We don't need any per-node values right now.

# /etc/puppetlabs/code/environments/production/data/groups/ci/prod.yaml
profile::jenkins::master::jenkins_port: '80'
Write a role
To write roles, we consider the machines we’ll be managing and decide what else they need in addition to that Jenkins profile.

Our Jenkins masters don’t serve any other purpose. But we have some profiles (code not shown) that we expect every machine in our fleet to have:

- **profile::base** must be assigned to every machine, including workstations. It manages basic policies, and uses some conditional logic to include OS-specific profiles as needed.
- **profile::server** must be assigned to every machine that provides a service over the network. It makes sure ops can log into the machine, and configures things like timekeeping, firewalls, logging, and monitoring.

So a role to manage one of our Jenkins masters should include those classes as well.

```plaintext
class role::jenkins::master {
    include profile::base
    include profile::server
    include profile::jenkins::master
}
```

Related information

**Rules for role classes** on page 335

There are rules for writing role classes.

Assign the role to nodes
Finally, we assign `role::jenkins::master` to every node that acts as a Jenkins master.

Puppet has several ways to assign classes to nodes, so use whichever tool you feel best fits your team. Your main choices are:

- The console node classifier, which lets you group nodes based on their facts and assign classes to those groups.
- The main manifest which can use node statements or conditional logic to assign classes.
- **Hiera** or Puppet lookup — Use the `lookup` function to do a unique array merge on a special `classes` key, and pass the resulting array to the `include` function.

```plaintext
# /etc/puppetlabs/code/environments/production/manifests/site.pp
lookup('classes', {merge => unique}).include
```

Designing advanced profiles

In this advanced example, we iteratively refactor our basic roles and profiles example to handle real-world concerns. The final result is — with only minor differences — the Jenkins profile we use in production here at Puppet.

Along the way, we explain our choices and point out some of the common trade-offs you encounter as you design your own profiles.

Here's the basic Jenkins profile we're starting with:

```plaintext
# /etc/puppetlabs/code/environments/production/site/profile/manifests/jenkins/master.pp
class profile::jenkins::master (String $jenkins_port = '9091', String $java_dist = 'jdk', String $java_version = 'latest',
```
class { 'jenkins':
    configure_firewall => true,
    install_java       => false,
    port               => $jenkins_port,
    config_hash        => {
        'HTTP_PORT' => { 'value' => $jenkins_port },
        'JENKINS_PORT' => { 'value' => $jenkins_port },
    },
}

class { 'java':
    distribution => $java_dist,
    version      => $java_version,
    before       => Class['jenkins'],
}

Related information
Rules for profile classes on page 335
There are rules for writing profile classes.

First refactor: Split out Java
We want to manage Jenkins masters and Jenkins agent nodes. We won't cover agent profiles in detail, but the first issue we encountered is that they also need Java.

We could copy and paste the Java class declaration; it's small, so keeping multiple copies up-to-date might not be too burdensome. But instead, we decided to break Java out into a separate profile. This way we can manage it one time, then include the Java profile in both the agent and master profiles.

Note: This is a common trade-off. Keeping a chunk of code in only one place (often called the DRY — "don't repeat yourself" — principle) makes it more maintainable and less vulnerable to rot. But it has a cost: your individual profile classes become less readable, and you must view more files to see what a profile actually does. To reduce that readability cost, try to break code out in units that make inherent sense. In this case, the Java profile's job is simple enough to guess by its name — your colleagues don't have to read its code to know that it manages Java 8. Comments can also help.

First, decide how configurable Java needs to be on Jenkins machines. After looking at our past usage, we realized that we use only two options: either we install Oracle's Java 8 distribution, or we default to OpenJDK 7, which the Jenkins module manages. This means we can:

• Make our new Java profile really simple: hardcode Java 8 and take no configuration.
• Replace the two Java parameters from profile::jenkins::master with one Boolean parameter (whether to let Jenkins handle Java).

Note: This is rule 4 in action. We reduce our profile's configuration surface by combining multiple questions into one.

Here's the new parameter list:

class profile::jenkins::master (  
    String $jenkins_port = '9091',  
    Boolean $install_jenkins_java = true,
) { # ...

And here's how we choose which Java to use:

class { 'jenkins':
    configure_firewall => true,
    install_java       => $install_jenkins_java,  # <--- here
    port               => $jenkins_port,
}
config_hash => {
    'HTTP_PORT' => { 'value' => $jenkins_port },
    'JENKINS_PORT' => { 'value' => $jenkins_port },
},

# When not using the jenkins module's java version, install java8.
unless $install_jenkins_java { include profile::jenkins::usage::java8 }

And our new Java profile:

::jenkins::usage::java8
# Sets up java8 for Jenkins on Debian
#
class profile::jenkins::usage::java8 {
    motd::register { 'Java usage profile (profile::jenkins::usage::java8)'; }
    # OpenJDK 7 is already managed by the Jenkins module.
    # ::jenkins::install_java or ::jenkins::agent::install_java should be
    # this can be set through the class parameter $install_jenkins_java
    case $::osfamily {
        'debian': {  
            class { 'java':
                distribution => 'oracle-jdk8',
                version      => '8u92',
            }
            package { 'tzdata-java':
                ensure => latest,
            }
        }
    default: {
        notify { "profile::jenkins::usage::java8 cannot set up JDK on
        ${::osfamily}"; }
    }
}

Second refactor: Manage the heap

At Puppet, we manage the Java heap size for the Jenkins app. Production servers didn't have enough memory for heavy use.

The Jenkins module has a jenkins::sysconfig defined type for managing system properties, so let's use it:

```erb
# Manage the heap size on the master, in MB.
if($::memorysize_mb =~ Number and $::memorysize_mb > 8192)
{
  # anything over 8GB we should keep max 4GB for OS and others
  $heap = sprintf('%0.0f', $::memorysize_mb - 4096)
} else {
  # This is calculated as 50% of the total memory.
  $heap = sprintf('%0.0f', $::memorysize_mb * 0.5)
}

# Set java params, like heap min and max sizes. See
# https://wiki.jenkins-ci.org/display/JENKINS/Features+controlled+by
+system+properties
jenkins::sysconfig { 'JAVA_ARGS':
  value => "-Xms$heapm -Xmx$heapm -Djava.awt.headless=true
}"
```

Note: Rule 4 again — we couldn't hardcode this, because we have some smaller Jenkins masters that can't spare the extra memory. But because our production masters are always on more powerful machines, we can calculate the heap based on the machine's memory size, which we can access as a fact. This lets us avoid extra configuration.

Third refactor: Pin the version
We dislike surprise upgrades, so we pin Jenkins to a specific version. We do this with a direct package URL instead of by adding Jenkins to our internal package repositories. Your organization might choose to do it differently.

First, we add a parameter to control upgrades. Now we can set a new value in .../data/groups/ci/dev.yaml while leaving .../data/groups/ci.yaml alone — our dev machines get the new Jenkins version first, and we can ensure everything works as expected before upgrading our prod machines.

class profile::jenkins::master (  
  Variant[String[1], Boolean] $direct_download = 'http://pkg.jenkins-ci.org/debian-stable/binary/jenkins_1.642.2_all.deb',  
  # ...  ) { # ...  

Then, we set the necessary parameters in the Jenkins class:

class { 'jenkins':  
  lts => true,    # <-- here  
  repo => true,   # <-- here  
  direct_download => $direct_download,  # <-- here  
  version => 'latest',  # <-- here  
  service_enable => true,  
  service_ensure => running,  
  configure_firewall => true,  
  install_java => $install_jenkins_java,  
  port => $jenkins_port,  
  config_hash => {  
    'HTTP_PORT' => { 'value' => $jenkins_port },  
    'JENKINS_PORT' => { 'value' => $jenkins_port },  
  },  
}

This was a good time to explicitly manage the Jenkins service, so we did that as well.

Fourth refactor: Manually manage the user account

We manage a lot of user accounts in our infrastructure, so we handle them in a unified way. The profile::server class pulls in virtual::users, which has a lot of virtual resources we can selectively realize depending on who needs to log into a given machine.

**Note:** This has a cost — it's action at a distance, and you need to read more files to see which users are enabled for a given profile. But we decided the benefit was worth it: because all user accounts are written in one or two files, it's easy to see all the users that might exist, and ensure that they're managed consistently.

We're accepting difficulty in one place (where we can comfortably handle it) to banish difficulty in another place (where we worry it would get out of hand). Making this choice required that we know our colleagues and their comfort zones, and that we know the limitations of our existing code base and supporting services.

So, for this example, we change the Jenkins profile to work the same way: we manage the jenkins user alongside the rest of our user accounts. While we're doing that, we also manage a few directories that can be problematic depending on how Jenkins is packaged.

Some values we need are used by Jenkins agents as well as masters, so we're going to store them in a params class, which is a class that sets shared variables and manages no resources. This is a heavyweight solution, so wait until it provides real value before using it. In our case, we had a lot of OS-specific agent profiles (not shown in these examples), and they made a params class worthwhile.

**Note:** Just as before, "don't repeat yourself" is in tension with "keep it readable." Find the balance that works for you.
Three things to notice in the code above:

- We manage users with a homegrown `account::user` defined type, which declares a `user` resource plus a few other things.
- We use an `Account::User` resource collector to realize the Jenkins user. This relies on `profile::server` being declared.
- We set the Jenkins class's `manage_user`, `manage_group`, and `manage_datadirs` parameters to false.
- We're now explicitly managing the plugins directory and the run directory.

Fifth refactor: Manage more dependencies

Jenkins always needs Git installed (because we use Git for source control at Puppet), and it needs SSH keys to access private Git repos and run commands on Jenkins agent nodes. We also have a standard list of Jenkins plugins we use, so we manage those too.

Managing Git is pretty easy:

```puppet
package { 'git':
  ensure => present,
}
```

SSH keys are less easy, because they are sensitive content. We can’t check them into version control with the rest of our Puppet code, so we put them in a custom mount point on one specific Puppet server.

Because this server is different from our normal Puppet servers, we made a rule about accessing it: you must look up the hostname from data instead of hardcoding it. This lets us change it in only one place if the secure server ever moves.

```puppet
$secure_server = lookup('puppetlabs::ssl::secure_server')

file { "${master_config_dir}/.ssh":
  ensure => directory,
  owner  => $jenkins_owner,
  group  => $jenkins_group,
  mode   => '0700',
}

file { "${master_config_dir}/.ssh/id_rsa":
  ensure => file,
  owner  => $jenkins_owner,
  group  => $jenkins_group,
  mode   => '0600',
  source => "puppet://$secure_server/secure/delivery/id_rsa-jenkins",
}

file { "${master_config_dir}/.ssh/id_rsa.pub":
  ensure => file,
  owner  => $jenkins_owner,
  group  => $jenkins_group,
  mode   => '0640',
  source => "puppet://$secure_server/secure/delivery/id_rsa-jenkins.pub",
}
```

Plugins are also a bit tricky, because we have a few Jenkins masters where we want to manually configure plugins. So we put the base list in a separate profile, and use a parameter to control whether we use it.

```puppet
class profile::jenkins::master ( Boolean $manage_plugins = false, # ... ) {
  # ...
  if $manage_plugins {
    include profile::jenkins::master::plugins
  }
}
```
In the plugins profile, we can use the `jenkins::plugin` resource type provided by the Jenkins module.

```puppet
# /etc/puppetlabs/code/environments/production/site/profile/manifests/jenkins/master/plugins.pp
class profile::jenkins::master::plugins {
  jenkins::plugin { 'audit2db':          }
  jenkins::plugin { 'credentials':       }
  jenkins::plugin { 'jquery':            }
  jenkins::plugin { 'job-import-plugin': }
  jenkins::plugin { 'ldap':              }
  jenkins::plugin { 'mailer':            }
  jenkins::plugin { 'metadata':          }
  # ... and so on.
}
```

    +      ensure => directory,
```
Sixth refactor: Manage logging and backups

Backing up is usually a good idea.

We can use our homegrown backup module, which provides a backup::job resource type (profile::server takes care of its prerequisites). But we should make backups optional, so people don't accidentally post junk to our backup server if they're setting up an ephemeral Jenkins instance to test something.

```plaintext
class profile::jenkins::master (
    Boolean $backups_enabled = false,
    # ...
) {
    # ...
    if $backups_enabled {
        backup::job { "jenkins-data-${::hostname}":
            files => $master_config_dir,
        }
    }
}
```

Also, our teams gave us some conflicting requests for Jenkins logs:

- Some people want it to use syslog, like most other services.
- Others want a distinct log file so syslog doesn't get spammed, and they want the file to rotate more quickly than it does by default.

That implies a new parameter. We can make one called $jenkins_logs_to_syslog and default it to undef. If you set it to a standard syslog facility (like daemon.info), Jenkins logs there instead of its own file.

We use jenkins::sysconfig and our homegrown logrotate::job to do the work:

```plaintext
class profile::jenkins::master (
    Optional[String[1]] $jenkins_logs_to_syslog = undef,
    # ...
) {
    # ...
    if $jenkins_logs_to_syslog {
        jenkins::sysconfig { 'JENKINS_LOG':
            value => "${jenkins_logs_to_syslog",
        }
    }
}
```

Seventh refactor: Use a reverse proxy for HTTPS

We want the Jenkins web interface to use HTTPS, which we can accomplish with an Nginx reverse proxy. We also want to standardize the ports: the Jenkins app always binds to its default port, and the proxy always serves over 443 for HTTPS and 80 for HTTP.

If we want to keep vanilla HTTP available, we can provide an $ssl parameter. If set to false (the default), you can access Jenkins via both HTTP and HTTPS. We can also add a $site_alias parameter, so the proxy can listen on a hostname other than the node’s main FQDN.

```bash
class profile::jenkins::master (  
  Boolean $ssl = false,  
  Optional[String[1]] $site_alias = undef,  
  # IMPORTANT: notice that $jenkins_port is removed.  
  # ...
)
```

Set configure_firewall => false in the Jenkins class:

```bash
class {  
  'jenkins':    
    lts => true,  
    repo => true,  
    direct_download => $direct_download,  
    version => 'latest',  
    service_enable => true,  
    service_ensure => running,  
    configure_firewall => false,  
    install_java => $install_jenkins_java,  
    manage_user => false,  
    manage_group => false,  
    manage_datadirs => false,  
    # IMPORTANT: notice that port and config_hash are removed.  
}
```

We need to deploy SSL certificates where Nginx can reach them. Because we serve a lot of things over HTTPS, we already had a profile for that:

```bash
# Deploy the SSL certificate/chain/key for sites on this domain.  
include profile::ssl::delivery_wildcard
```

This is also a good time to add some info for the message of the day, handled by puppetlabs/motd:

```bash
motd::register {  
  'Jenkins CI master (profile::jenkins::master)':  
}
```
if $site_alias {
    motd::register { 'jenkins-site-alias':
        content => @("END"),
        profile::jenkins::master::proxy
        Jenkins site alias: ${site_alias}
    }-END
    order => 25,
}

The bulk of the work is handled by a new profile called profile::jenkins::master::proxy. We're omitting the code for brevity; in summary, what it does is:

- Include profile::nginx.
- Use resource types from the jfryman/nginx to set up a vhost, and to force a redirect to HTTPS if we haven't enabled vanilla HTTP.
- Set up logstash forwarding for access and error logs.
- Include profile::fw::https to manage firewall rules, if necessary.

Then, we declare that profile in our main profile:

class { 'profile::jenkins::master::proxy':
    site_alias  => $site_alias,
    require_ssl => $ssl,
}

Important:

We are now breaking rule 1, the most important rule of the roles and profiles method. Why?

Because profile::jenkins::master::proxy is a "private" profile that belongs solely to profile::jenkins::master. It will never be declared by any role or any other profile.

This is the only exception to rule 1: if you're separating out code for the sole purpose of readability --- that is, if you could paste the private profile's contents into the main profile for the exact same effect --- you can use a resource-like declaration on the private profile. This lets you consolidate your data lookups and make the private profile's inputs more visible, while keeping the main profile a little cleaner. If you do this, you must make sure to document that the private profile is private.

If there is any chance that this code might be reused by another profile, obey rule 1.

  ]
}
Designing convenient roles

There are several approaches to building roles, and you must decide which ones are most convenient for you and your team.

High-quality roles strike a balance between readability and maintainability. For most people, the benefit of seeing the entire role in a single file outweighs the maintenance cost of repetition. Later, if you find the repetition burdensome, you can change your approach to reduce it. This might involve combining several similar roles into a more complex role, creating sub-roles that other roles can include, or pushing more complexity into your profiles.

So, begin with granular roles and deviate from them only in small, carefully considered steps.

Here's the basic Jenkins role we're starting with:

```ruby
class role::jenkins::master {
  include profile::base
  include profile::server
  include profile::jenkins::master
}
```

**Related information**

- **Rules for role classes** on page 335

There are rules for writing role classes.

**First approach: Granular roles**

The simplest approach is to make one role per type of node, period. For example, the Puppet Release Engineering (RE) team manages some additional resources on their Jenkins masters.

With granular roles, we'd have at least two Jenkins master roles. A basic one:

```ruby
class role::jenkins::master {
  include profile::base
  include profile::server
  include profile::jenkins::master
}
```

...and an RE-specific one:

```ruby
class role::jenkins::master::release {
  include profile::base
  include profile::server
  include profile::jenkins::master
  include profile::jenkins::master::release
}
```

The benefits of this setup are:

- **Readability** — By looking at a single class, you can immediately see which profiles make up each type of node.
- **Simplicity** — Each role is just a linear list of profiles.

Some drawbacks are:
• Role bloat — If you have a lot of only-slightly-different nodes, you quickly have a large number of roles.
• Repetition — The two roles above are almost identical, with one difference. If they're two separate roles, it's harder to see how they're related to each other, and updating them can be more annoying.

**Second approach: Conditional logic**
Alternatively, you can use conditional logic to handle differences between closely-related kinds of nodes.

class role::jenkins::master::release {
  include profile::base
  include profile::server
  include profile::jenkins::master

  if $facts['group'] == 'release' {
    include profile::jenkins::master::release
  }
}

The benefits of this approach are:
• You have fewer roles, and they're easy to maintain.

The drawbacks are:
• Reduced readability...maybe. Conditional logic isn't usually hard to read, especially in a simple case like this, but you might feel tempted to add a bunch of new custom facts to accommodate complex roles. This can make roles much harder to read, because a reader must also know what those facts mean.

  In short, be careful of turning your node classification system inside-out. You might have a better time if you separate the roles and assign them with your node classifier.

**Third approach: Nested roles**
Another way of reducing repetition is to let roles include other roles.

class role::jenkins::master {
  # Parent role:
  include role::server
  # Unique classes:
  include profile::jenkins::master
}

class role::jenkins::master::release {
  # Parent role:
  include role::jenkins::master
  # Unique classes:
  include profile::jenkins::master::release
}

In this example, we reduce boilerplate by having role::jenkins::master include role::server. When role::jenkins::master::release includes role::jenkins::master, it automatically gets role::server as well. With this approach, any given role only needs to:
• Include the "parent" role that it most resembles.
• Include the small handful of classes that differentiate it from its parent.

The benefits of this approach are:
• You have fewer roles, and they're easy to maintain.
• Increased visibility in your node classifier.

The drawbacks are:
• Reduced readability: You have to open more files to see the real content of a role. This isn't much of a problem if you go only one level deep, but it can get cumbersome around three or four.
Fourth approach: Multiple roles per node
In general, we recommend that you assign only one role to a node. In an infrastructure where nodes usually provide one primary service, that's the best way to work.

However, if your nodes tend to provide more than one primary service, it can make sense to assign multiple roles.

For example, say you have a large application that is usually composed of an application server, a database server, and a web server. To enable lighter-weight testing during development, you've decided to provide an "all-in-one" node type to your developers. You could do this by creating a new role::our_application::monolithic class, which includes all of the profiles that compose the three normal roles, but you might find it simpler to use your node classifier to assign all three roles (role::our_application::app, role::our_application::db, and role::our_application::web) to those all-in-one machines.

The benefit of this approach are:

• You have fewer roles, and they're easy to maintain.

The drawbacks are:

• There's no actual "role" that describes your multi-purpose nodes; instead, the source of truth for what's on them is spread out between your roles and your node classifier, and you must cross-reference to understand their configurations. This reduces readability.

• The normal and all-in-one versions of a complex application are likely to have other subtle differences you need to account for, which might mean making your "normal" roles more complex. It's possible that making a separate role for this kind of node would reduce your overall complexity, even though it increases the number of roles and adds repetition.

Fifth approach: Super profiles
Because profiles can already include other profiles, you can decide to enforce an additional rule at your business: all profiles must include any other profiles needed to manage a complete node that provides that service.

For example, our profile::jenkins::master class could include both profile::server and profile::base, and you could manage a Jenkins master server by directly assigning profile::jenkins::master in your node classifier. In other words, a "main" profile would do all the work that a role usually does, and the roles layer would no longer be necessary.

The benefits of this approach are:

• The chain of dependencies for a complex service can be more clear this way.

• Depending on how you conceptualize code, this can be easier in a lot of ways!

The drawbacks are:

• Loss of flexibility. This reduces the number of ways in which your roles can be combined, and reduces your ability to use alternate implementations of dependencies for nodes with different requirements.

• Reduced readability, on a much grander scale. Like with nested roles, you lose the advantage of a clean, straightforward list of what a node consists of. Unlike nested roles, you also lose the clear division between "top-level" complete system configurations (roles) and "mid-level" groupings of technologies (profiles). Not every profile makes sense as an entire system, so you some way to keep track of which profiles are the top-level ones.

Some people really find continuous hierarchies easier to reason about than sharply divided layers. If everyone in your organization is on the same page about this, a "profiles and profiles" approach might make sense. But we strongly caution you against it unless you're very sure; for most people, a true roles and profiles approach works better. Try the well-traveled path first.

Sixth approach: Building roles in the node classifier
Instead of building roles with the Puppet language and then assigning them to nodes with your node classifier, you might find your classifier flexible enough to build roles directly.

For example, you might create a "Jenkins masters" group in the console and assign it the profile::base, profile::server, and profile::jenkins::master classes, doing much the same job as our basic role::jenkins::master class.
Important:

If you're doing this, make sure you don't set parameters for profiles in the classifier. Continue to use Hiera / Puppet lookup to configure profiles.

This is because profiles are allowed to include other profiles, which interacts badly with the resource-like behavior that node classifiers use to set class parameters.

The benefits of this approach are:

• Your node classifier becomes much more powerful, and can be a central point of collaboration for managing nodes.
• Increased readability: A node's page in the console displays the full content of its role, without having to cross-reference with manifests in your role module.

The drawbacks are:

• Loss of flexibility. The Puppet language's conditional logic is often more flexible and convenient than most node classifiers, including the console.
• Your roles are no longer in the same code repository as your profiles, and it's more difficult to make them follow the same code promotion processes.

Node classifier API v1

These are the endpoints for the node classifier v1 API.

Tip: In addition to these endpoints, you can use the status API to check the health of the node classifier service.

• Forming node classifier requests on page 359
  Requests to the node classifier API must be well-formed HTTP(S) requests.
• Groups endpoint on page 361
  The groups endpoint is used to create, read, update, and delete groups.
• Groups endpoint examples on page 378
  Use example requests to better understand how to work with groups in the node classifier API.
• Classes endpoint on page 380
  Use the classes endpoints to retrieve lists of classes, including classes with specific environments. The output from this endpoint is especially useful for creating new node groups, which usually contain a reference to one or more classes.
• Classification endpoint on page 382
  The classification endpoint takes a node name and a set of facts, and returns information about how that node is classified. The output can help you test your classification rules.
• Commands endpoint on page 392
  Use the commands endpoint to unpin specified nodes from all groups they’re pinned to.
• Environments endpoint on page 393
  Use the environments endpoint to retrieve information about environments in the node classifier. The output tells you either which environments are available or whether a named environment exists. The output can be helpful when creating new node groups, which must be associated with an environment. The node classifier gets its information about environments from Puppet, so do not use this endpoint to create, update, or delete them.

© 2020 Puppet, Inc.
• **Nodes check-in history endpoint** on page 394
  Use the `nodes` endpoint to retrieve historical information about nodes that have checked into the node classifier.

• **Group children endpoint** on page 397
  Use the group children endpoint to retrieve a specified group and its descendents.

• **Rules endpoint** on page 401
  Use the rules endpoint to translate a group’s rule condition into PuppetDB query syntax.

• **Import hierarchy endpoint** on page 402
  Use the import hierarchy endpoint to delete all existing node groups from the node classifier service and replace them with the node groups in the body of the submitted request.

• **Last class update endpoint** on page 403
  Use the last class update endpoint to retrieve the time that classes were last updated from the Puppet master.

• **Update classes endpoint** on page 403
  Use update classes endpoint to trigger the node classifier to update class and environment definitions from the Puppet master.

• **Validation endpoints** on page 404
  Use validation endpoints to validate groups in the node classifier.

• **Node classifier errors** on page 407
  Familiarize yourself with error responses to make working the node classifier service API easier.

### Related information
- **API index** on page 33
  APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

### Forming node classifier requests
Requests to the node classifier API must be well-formed HTTP(S) requests.

By default, the node classifier service listens on port 4433 and all endpoints are relative to the `/classifier-api/` path. For example, the full URL for the `/v1/groups` endpoint on localhost would be `https://localhost:4433/classifier-api/v1/groups`.

If needed, you can change the port the classifier API listens on.

### Related information
- **Configuring and tuning the console** on page 158
  After installing Puppet Enterprise, you can change product settings to customize the console’s behavior, adjust to your team’s needs, and improve performance. Many settings can be configured in the console itself.

### Authenticating to the node classifier API
You need to authenticate requests to the node classifier API. You can do this using RBAC authentication tokens or with the RBAC certificate whitelist.

### Authentication token
You can make requests to the node classifier API using RBAC authentication tokens.

For detailed information about authentication tokens, see token-based authentication.

In the this example, we are using the `/groups` endpoint of the node classifier API to get a list of all groups that exist in the node classifier, along with their associated metadata. The example assumes that you have already generated a token with `puppet-access login`.

**Bash**

```bash
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups"
curl --insecure --header "$auth_header" "$uri"
```

© 2020 Puppet, Inc.
The example above uses the X-Authentication header to supply the token information. In some cases, such as GitHub webhooks, you might need to supply the token in a token parameter. To supply the token in a token parameter, you would specify the request like this:

Bash

```bash
uri="https://$(puppet config print server):4433/classifier-api/v1/groups?token=$(puppet-access show)"
curl --insecure "$uri"
```

**Note:** Supplying the token as a token parameter is not as secure as using the X-Authentication method.

**Whitelisted certificate**

You can also authenticate requests using a certificate listed in RBAC's certificate whitelist. The RBAC whitelist is located at `/etc/puppetlabs/console-services/rbac-certificate-whitelist`. If you edit this file, you must reload the `pe-console-services` service for your changes to take effect (`sudo service pe-console-services reload`). You can attach the certificate using the command line as demonstrated in the example cURL query below. You must have the whitelist certificate name and the private key to run the script.

The following query returns a list of all groups that exist in the node classifier, along with their associated metadata. This query shows how to attach the whitelist certificate to authenticate the node classifier API.

In this query, the "whitelisted certname" needs to match a name in the file, `/etc/puppetlabs/console-services/rbac-certificate-whitelist`.

Bash

```bash
type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server:4433/classifier-api/v1/groups"
curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key" "$uri"
```

You do not need to use an agent certificate for authentication. You can use `puppet cert generate` to create a new certificate specifically for use with the API.

**Related information**

[Token-based authentication](#) on page 208

Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

**Using pagination parameters**

If you have a large number of groups, classes, nodes, node check-ins, or environments, then sending a GET request through the classifier API could return an excessively large number of items.

To limit the number of items returned, you can use the `limit` and `offset` parameters.

- **limit:** The value of the `limit` parameter limits how many items are returned in a response. The value must be a non-negative integer. If you specify a value other than a non-negative integer, you get a 400 Bad Request error.
- **offset:** The value of the `offset` parameter specifies the number of item that are skipped. For example, if you specify an offset of 20 with a limit of 10, as shown in the example below, the first 20 items are skipped and you get back item 21 through to item 30. The value must be a non-negative integer. If you specify a value other than a non-negative integer, you get a 400 Bad Request error.
The following example shows a request using the limit and offset parameters.

**Bash**

```bash

type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups?
limit=10&offset=20"

curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key $key "$uri"
```

**Groups endpoint**

The groups endpoint is used to create, read, update, and delete groups.

A group belongs to an environment, applies classes (possibly with parameters), and matches nodes based on rules. Because groups are so central to the classification process, this endpoint is where most of the action is.

**GET /v1/groups**

Use the /v1/groups endpoint to retrieve a list of all node groups in the node classifier.

**Query parameters**

The request accepts these parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>inherited</td>
<td>If set to any value besides 0 or false, the node group includes the classes, class parameters, configuration data, and variables that it inherits from its ancestors.</td>
</tr>
</tbody>
</table>

**Response format**

The response is a JSON array of node group objects, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node group (a string).</td>
</tr>
<tr>
<td>id</td>
<td>The node group's ID, which is a string containing a type-4 (random) UUID. The regular expression used to validate node group UUIDs is <code>[0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12}</code>.</td>
</tr>
<tr>
<td>description</td>
<td>An optional key containing an arbitrary string describing the node group.</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the node group's environment (a string), which indirectly defines what classes are available for the node group to set, and is the environment that nodes classified into this node group run under.</td>
</tr>
</tbody>
</table>
### Key Definition

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment_trumps</td>
<td>This is a boolean that changes the behavior of classifications that this node group is involved in. The default behavior is to return a classification-conflict error if the node groups that a node is classified into do not all have the same environment. If this flag is set, then this node group's environment overrides the environments of the other node groups (provided that none of them also have this flag set), with no attempt made to validate that the other node groups' classes and class parameters exist in this node group's environment.</td>
</tr>
<tr>
<td>parent</td>
<td>The ID of the node group's parent (a string). A node group is not permitted to be its own parent, unless it is the All Nodes group, which is the root of the hierarchy. Note that the root group always has the lowest-possible random UUID, 00000000-0000-4000-8000-000000000000.</td>
</tr>
<tr>
<td>rule</td>
<td>A boolean condition on node properties. When a node's properties satisfy this condition, it's classified into the node group.</td>
</tr>
<tr>
<td>classes</td>
<td>An object that defines both the classes consumed by nodes in this node group and any non-default values for their parameters. The keys of the object are the class names, and the values are objects describing the parameters. The parameter objects' keys are parameter names, and the values are what the node group sets for that parameter (always a string).</td>
</tr>
<tr>
<td>config_data</td>
<td>An object similar to the classes object that specifies parameters that are applied to classes if the class is assigned in the classifier or in puppet code. The keys of the object are the class names, and the values are objects describing the parameters. The parameter objects' keys are parameter names, and the values are what the group sets for that parameter (always a string). This feature is enabled/disabled via the classifier::allow-config-data setting. When set to false, this key is stripped from the payload.</td>
</tr>
</tbody>
</table>
### Key | Definition
--- | ---
**deleted** | An object similar to the classes object that shows which classes and class parameters set by the node group have since been deleted. If none of the node group’s classes or parameters have been deleted, this key is not present, so checking the presence of this key is an easy way to check whether the node group has references that need updating. The keys of this object are class names, and the values are further objects. These secondary objects always contain the puppetlabs.classifier/deleted key, whose value is a Boolean indicating whether the entire class has been deleted. The other keys of these objects are parameter names, and the other values are objects that always contain two keys: puppetlabs.classifier/deleted, mapping to a boolean indicating whether the specific class parameter has been deleted; and value, mapping to the string value set by the node group for this parameter (the value is duplicated for convenience, as it also appears in the classes object).

**variables** | An object that defines the values of any top-level variables set by the node group. The object is a mapping between variable names and their values (which can be any JSON value).

**last_edited** | The most recent time at which a user committed changes to a node group. This is a time stamp in ISO 8601 format, YYYY-MM-DDTHH:MM:SSZ.

**serial_number** | A number assigned to a node group. This number is incremented each time changes to a group are committed. serial_number is used to prevent conflicts when multiple users make changes to the same node group at the same time.

This example shows a node group object:

```json
{
    "name": "Webservers",
    "id": "fc500c43-5065-469b-91fc-37ed0e500e81",
    "last_edited": "2018-02-20T02:36:17.776Z",
    "serial_number": 16,
    "environment": "production",
    "description": "This group captures configuration relevant to all web-facing production webbservers, regardless of location.",
    "parent": "00000000-0000-4000-8000-000000000000",
    "rule": ["and", ["~", ["trusted", "certname"], "www"], [">=", ["fact", "total_ram"], 512]],
    "classes": {
        "apache": {
            "serveradmin": "bofh@travaglia.net",
            "keepalive_timeout": "5"
        }
    },
    "config_data": {
```

© 2020 Puppet, Inc.
This example shows a node group object that refers to some classes and parameters that have been deleted:

```json
{
    "name": "Spaceship",
    "id": "fc500c43-5065-469b-91fc-37ed0e500e81",
    "last_edited": "2018-03-13T21:37:03.608Z",
    "serial_number": 42,
    "environment": "space",
    "parent": "00000000-0000-4000-8000-000000000000",
    "rule": ["=",
               ["fact", "is_spaceship"],
               "true"],
    "classes": {
        "payload": {
            "type": "cubesat",
            "count": "8",
            "mass": "10.64"
        },
        "rocket": {
            "stages": "3"
        }
    },
    "deleted": {
        "payload": {
            "puppetlabs.classifier/deleted": true,
            "rocket": {
                "puppetlabs.classifier/deleted": false,
                "stages": {
                    "puppetlabs.classifier/deleted": true,
                    "value": "3"
                }
            }
        }
    },
    "variables": {}
}
```

The entire `payload` class has been deleted, because its deleted parameters object's `puppetlabs.classifier/deleted` key maps to `true`, in contrast to the `rocket` class, which has had only its `stages` parameter deleted.

### Rule condition grammar

Nodes can be classified into groups using rules. This example shows how rule conditions must be structured:

```plaintext
condition  : [ (bool) (condition)+ ] | [ "not" (condition) ] | (operation)
bool        : "and" | "or"
operation   : [ (operator) (fact-path) (value) ]
operator    : "=" | "~" | ">" | ">=" | "<" | "<="
fact-path   : {field-name} | [ (path-type) {field-name} (path-component)+ ]
path-type    : "trusted" | "fact"
path-component : field-name | number
field-name   : string
```
For the regex operator "~", the value is interpreted as a Java regular expression. Literal backslashes must be used to escape regex characters in order to match those characters in the fact value.

For the numeric comparison operators (">", "\geq", "\leq", and "\leq") the fact value (which is always a string) is coerced to a number (either integral or floating-point). If the value can't be coerced to a number, the numeric operation evaluates to false.

For the fact path, the rule can be either a string representing a top level field (the only current meaningful value here would be "name" representing the node name) or a list of strings and indices that represent looking up a field in a nested data structure. When passing a list of strings or indices, the first and second entries in the list must be strings. Subsequent entries can be indices.

Regular facts start with "fact" (for example, ["fact", "architecture"]) and trusted facts start with "trusted" (for example, ["trusted", "certname"]).

**Error responses**

serial_number

If you commit a node group with a serial_number that an API call has previously assigned, the service returns a 409 Conflict response.

**POST /v1/groups**

Use the /v1/groups endpoint to create a new node group without specifying its ID. When you use this endpoint, the node classifier service randomly generates an ID.

**Request format**

The request body must be a JSON object describing the node group to be created. The request uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node group (a string).</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the node group's environment. This key is optional; if it's not provided, the default environment (production) is used.</td>
</tr>
<tr>
<td>environment_trumps</td>
<td>Whether this node group's environment should override those of other node groups at classification-time. This key is optional; if it's not provided, the default value of false is used.</td>
</tr>
<tr>
<td>description</td>
<td>A string describing the node group. This key is optional; if it's not provided, the node group has no description and this key doesn't appear in responses.</td>
</tr>
<tr>
<td>parent</td>
<td>The ID of the node group's parent (required).</td>
</tr>
<tr>
<td>rule</td>
<td>The condition that must be satisfied for a node to be classified into this node group</td>
</tr>
<tr>
<td>variables</td>
<td>An object that defines the names and values of any top-level variables set by the node group. The keys of the object are the variable names, and the corresponding value is that variable's value, which can be any sort of JSON value. The variables key is optional, and if a node group does not define any top-level variables then it may be omitted.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>classes</td>
<td>An object that defines the classes to be used by nodes in the node group. The classes key is required, and at minimum should be an empty object ({}). The classes key also contains the parameters for each class. Some classes have required parameters. This is a two-level object; that is, the keys of the object are class names (strings), and each key's value is another object that defines class parameter values. This innermost object maps between class parameter names and their values. The keys are the parameter names (strings), and each value is the parameter's value, which can be any kind of JSON value. The classes key is not optional; if it is missing, the service returns a 400 Bad Request response.</td>
</tr>
<tr>
<td>config_data</td>
<td>An optional object that defines the class parameters to be used by nodes in the group. Its structure is the same as the classes object. If you use a config_data key but provide only the class, like &quot;config_data&quot;: {&quot;qux&quot;:{}}, no configuration data is stored. Note: This feature is enabled with the classifier::allow-config-data setting. When set to false, the presence of this key in the payload results in a 400 response.</td>
</tr>
</tbody>
</table>

### Response format

If the node group was successfully created, the service returns a 303 See Other response, with the path to retrieve the created node group in the "location" header of the response.

### Error responses

Responses and keys returned for create group requests depend on the type of error.

#### schema-violation

If any of the required keys are missing or the values of any of the defined keys do not match the required type, the service returns a 400 Bad Request response using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;schema-violation&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains three keys:</td>
</tr>
<tr>
<td></td>
<td>• submitted — Describes the submitted object.</td>
</tr>
<tr>
<td></td>
<td>• schema — Describes the schema that object is expected to conform to.</td>
</tr>
<tr>
<td></td>
<td>• error — Describes how the submitted object failed to conform to the schema.</td>
</tr>
</tbody>
</table>

#### malformed-request

If the request's body could not be parsed as JSON, the service returns a 400 Bad Request response using these keys:
### kind

"malformed-request"

### details

An object that contains two keys:
- **body** — Holds the request body that was received.
- **error** — Describes how the submitted object failed to conform to the schema.

#### uniqueness-violation

If your attempt to create the node group violates uniqueness constraints (such as the constraint that each node group name must be unique within its environment), the service returns a 422 Unprocessable Entity response using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;uniqueness-violation&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Describes which fields of the node group caused the constraint to be violated, along with their values.</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains two keys:</td>
</tr>
<tr>
<td></td>
<td>• conflict — An object whose keys are the fields of the node group that violated the constraint and whose values are the corresponding field values.</td>
</tr>
<tr>
<td></td>
<td>• constraintName — The name of the database constraint that was violated.</td>
</tr>
</tbody>
</table>

#### missing-referents

If classes or class parameters defined by the node group, or inherited by the node group from its parent, do not exist in the submitted node group's environment, the service returns a 422 Unprocessable Entity response. In both cases the response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;missing-referents&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Describes the error and lists the missing classes or parameters.</td>
</tr>
<tr>
<td>details</td>
<td>An array of objects, where each object describes a single missing referent, and has the following keys:</td>
</tr>
<tr>
<td></td>
<td>• kind — &quot;missing-class&quot; or &quot;missing-parameter&quot;, depending on whether the entire class doesn't exist, or the class just doesn't have the parameter.</td>
</tr>
<tr>
<td></td>
<td>• missing — The name of the missing class or class parameter.</td>
</tr>
<tr>
<td></td>
<td>• environment — The environment that the class or parameter is missing from; that is, the environment of the node group where the error was encountered.</td>
</tr>
<tr>
<td></td>
<td>• group — The name of the node group where the error was encountered. Due to inheritance, this might not be the group where the parameter was defined.</td>
</tr>
<tr>
<td></td>
<td>• defined_by — The name of the node group that defines the class or parameter.</td>
</tr>
</tbody>
</table>
missing-parent

If the parent of the node group does not exist, the service returns a 422 Unprocessable Entity response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;missing-parent&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Shows the parent UUID that did not exist.</td>
</tr>
<tr>
<td>details</td>
<td>The full submitted node group.</td>
</tr>
</tbody>
</table>

inheritance-cycle

If the request causes an inheritance cycle, the service returns a 422 Unprocessable Entity response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;inheritance-cycle&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An array of node group objects that includes each node group involved in the cycle</td>
</tr>
<tr>
<td>msg</td>
<td>A shortened description of the cycle, including a list of the node group names with each followed by its parent until the first node group is repeated.</td>
</tr>
</tbody>
</table>

GET /v1/groups/<id>

Use the /v1/groups/<id> endpoint to retrieve a node group with the given ID.

Response format

The response is a JSON array of node group objects, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node group (a string).</td>
</tr>
<tr>
<td>id</td>
<td>The node group's ID, which is a string containing a type-4 (random) UUID. The regular expression used to validate node group UUIDs is [0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12}.</td>
</tr>
<tr>
<td>description</td>
<td>An optional key containing an arbitrary string describing the node group.</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the node group's environment (a string), which indirectly defines what classes are available for the node group to set, and is the environment that nodes classified into this node group run under.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>environment_trumps</td>
<td>This is a boolean that changes the behavior of classifications that this node group is involved in. The default behavior is to return a classification-conflict error if the node groups that a node is classified into do not all have the same environment. If this flag is set, then this node group's environment overrides the environments of the other node groups (provided that none of them also have this flag set), with no attempt made to validate that the other node groups' classes and class parameters exist in this node group's environment.</td>
</tr>
<tr>
<td>parent</td>
<td>The ID of the node group's parent (a string). A node group is not permitted to be its own parent, unless it is the All Nodes group, which is the root of the hierarchy. Note that the root group always has the lowest-possible random UUID, 00000000-0000-4000-8000-000000000000.</td>
</tr>
<tr>
<td>rule</td>
<td>A boolean condition on node properties. When a node's properties satisfy this condition, it's classified into the node group.</td>
</tr>
<tr>
<td>classes</td>
<td>An object that defines both the classes consumed by nodes in this node group and any non-default values for their parameters. The keys of the object are the class names, and the values are objects describing the parameters. The parameter objects' keys are parameter names, and the values are what the node group sets for those parameters (always a string).</td>
</tr>
<tr>
<td>deleted</td>
<td>An object similar to the classes object that shows which classes and class parameters set by the node group have since been deleted. If none of the node group's classes or parameters have been deleted, this key is not present, so checking the presence of this key is an easy way to check whether the node group has references that need updating. The keys of this object are class names, and the values are further objects. These secondary objects always contain the puppetlabs.classifier/deleted key, whose value is a Boolean indicating whether the entire class has been deleted. The other keys of these objects are parameter names, and the values are objects that always contain two keys: puppetlabs.classifier/deleted, mapping to a boolean indicating whether the specific class parameter has been deleted; and value, mapping to the string value set by the node group for this parameter (the value is duplicated for convenience, as it also appears in the classes object).</td>
</tr>
</tbody>
</table>
### Key Definition

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>variables</td>
<td>An object that defines the values of any top-level variables set by the node group. The object is a mapping between variable names and their values (which can be any JSON value).</td>
</tr>
<tr>
<td>last_edited</td>
<td>The most recent time at which a user committed changes to a node group. This is a time stamp in ISO 8601 format, <code>YYYY-MM-DDTHH:MM:SSZ</code>.</td>
</tr>
<tr>
<td>serial_number</td>
<td>A number assigned to a node group. This number is incremented each time changes to a group are committed. <code>serial_number</code> is used to prevent conflicts when multiple users make changes to the same node group at the same time.</td>
</tr>
</tbody>
</table>

### Error responses

If the node group with the given ID cannot be found, the service returns 404 Not Found and `malformed-uuid` responses. The body includes a generic 404 error response as described in the errors documentation.

#### serial_number

If you commit a node group with a `serial_number` that an API call has previously assigned, the service returns a 409 Conflict response.

### Related information

- Node classifier errors on page 407
- Familiarize yourself with error responses to make working the node classifier service API easier.

### PUT /v1/groups/<id>

Use the `/v1/groups/<id>` to create a node group with the given ID.

**CAUTION:** Any existing node group with the given ID is overwritten.

It is possible to overwrite an existing node group with a new node group definition that contains deleted classes or parameters.

**Important:** You must supply a valid type-4 (random) UUID for the ID.

### Request format

The request body must be a JSON object describing the node group to be created. The request uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node group (a string).</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the node group's environment. This key is optional; if it's not provided, the default environment (<code>production</code>) is used.</td>
</tr>
<tr>
<td>environment_trumps</td>
<td>Whether this node group's environment should override those of other node groups at classification-time. This key is optional; if it's not provided, the default value of <code>false</code> is used.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>description</td>
<td>A string describing the node group. This key is optional; if it's not provided, the node group has no description and this key doesn't appear in responses.</td>
</tr>
<tr>
<td>parent</td>
<td>The ID of the node group's parent (required).</td>
</tr>
<tr>
<td>rule</td>
<td>The condition that must be satisfied for a node to be classified into this node group</td>
</tr>
<tr>
<td>variables</td>
<td>An object that defines the names and values of any top-level variables set by the node group. The keys of the object are the variable names, and the corresponding value is that variable's value, which can be any sort of JSON value. The variables key is optional, and if a node group does not define any top-level variables then it may be omitted.</td>
</tr>
<tr>
<td>classes</td>
<td>An object that defines the classes to be used by nodes in the node group. The classes key is required, and at minimum should be an empty object ({}). The classes key also contains the parameters for each class. Some classes have required parameters. This is a two-level object; that is, the keys of the object are class names (strings), and each key's value is another object that defines class parameter values. This innermost object maps between class parameter names and their values. The keys are the parameter names (strings), and each value is the parameter's value, which can be any kind of JSON value. The classes key is not optional; if it is missing, the service returns a 400 Bad Request response.</td>
</tr>
</tbody>
</table>

**Response format**

If the node group is successfully created, the service returns a 201 Created response, with the node group object (in JSON) as the body. If the node group already exists and is identical to the submitted node group, then the service takes no action and returns a 200 OK response, again with the node group object as the body.

**Error responses**

If the requested node group object contains the id key, and its value differs from the UUID specified in the request's path, the service returns a 400 Bad Request response.

The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;conflicting-ids&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains two keys:</td>
</tr>
<tr>
<td></td>
<td>• submitted — Contains the ID submitted in the request body.</td>
</tr>
<tr>
<td></td>
<td>• fromUrl — Contains the ID taken from the request URL.</td>
</tr>
</tbody>
</table>
In addition, this operation can produce the general malformed-error response and any response that could also be generated by the POST group creation endpoint.

**POST /v1/groups/<id>**

Use the /v1/groups/<id> endpoint to update the name, environment, parent, rule, classes, class parameters, configuration data, and variables of the node group with the given ID by submitting a node group delta.

**Request format**

The request body must be JSON object describing the delta to be applied to the node group.

The classes, config data, variables, and rule keys of the delta are merged with the node group, and then any keys of the resulting object that have a null value are deleted. This allows you to remove classes, class parameters, configuration data, variables, or the rule from the node group by setting them to null in the delta.

If the delta has a rule key that’s set to a new value or nil, it’s updated wholesale or removed from the group accordingly.

The name, environment, description, and parent keys, if present in the delta, replace the old values wholesale with their values.

The serial_number key is optional. If you update a node group and provide the serial_number in the payload, and the serial_number is not the current one for that group, the service returns a 409 Conflict response. To bypass this check, omit the serial_number.

Note that the root group’s rule cannot be edited; any attempts to do so raise a 422 Unprocessable Entity response.

In the following examples, a delta is merged with a node group to update the group.

**Node group:**

```json
{
  "name": "Webservers",
  "id": "58463036-0efa-4365-b367-b5401c0711d3",
  "environment": "staging",
  "parent": "00000000-0000-4000-8000-000000000000",
  "rule": ["~", ["trusted", "certname"], "www"],
  "classes": {
    "apache": {
      "serveradmin": "bofh@travaglia.net",
      "keepalive_timeout": 5
    },
    "ssl": {
      "keystore": "/etc/ssl/keystore"
    }
  },
  "variables": {
    "ntp_servers": ["0.us.pool.ntp.org", "1.us.pool.ntp.org", "2.us.pool.ntp.org"]
  }
}
```

**Delta:**

```json
{
  "name": "Production Webservers",
  "id": "58463036-0efa-4365-b367-b5401c0711d3",
  "environment": "production",
  "parent": "01522c99-627c-4a07-b28e-a25dd563d756",
  "classes": {
    "apache": {
      "serveradmin": "roy@reynholm.co.uk",
```
Updated group:

```
{
  "name": "Production Webservers",
  "id": "58463036-0efa-4365-b367-b5401c0711d3",
  "environment": "production",
  "parent": "01522c99-627c-4a07-b28e-a25dd563d756",
  "rule": ["~", ["trusted", "certname"], "www"],
  "classes": {
    "apache": {
      "serveradmin": "roy@reynholm.co.uk"
    }
  },
  "variables": {
    "ntp_servers": ["0.us.pool.ntp.org", "1.us.pool.ntp.org", "2.us.pool.ntp.org"],
    "dns_servers": ["dns.reynholm.co.uk"]
  }
}
```

Note that the `ssl` class was deleted because its entire object was mapped to null, whereas for the `apache` class only the `keepalive_timeout` parameter was deleted.

### Deleted classes and class parameters

If the node group definition contains classes and parameters that have been deleted it is still possible to update the node group with those parameters and classes. Updates that don’t increase the number of errors associated with a node group are allowed.

### Error responses

The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;conflicting-ids&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains two keys:</td>
</tr>
<tr>
<td></td>
<td>• submitted — Contains the ID submitted in the request body.</td>
</tr>
<tr>
<td></td>
<td>• fromUrl — Contains the ID taken from the request URL.</td>
</tr>
</tbody>
</table>

If the requested node group object contains the `id` key, and its value differs from the UUID specified in the request’s path, the service returns a 400 Bad Request response.

In addition, this operation can produce the general `malformed-error` response and any response that could also be generated by the POST group creation endpoint.

422 responses to POST requests can include errors that were caused by the node group’s children, but a node group being created with a PUT request cannot have any children.
DELETE /v1/groups/<id>
Use the /v1/groups/<id> endpoint to delete the node group with the given ID.

Response format
If the delete operation is successful, the server returns a 204 No Content response.

Error responses
In addition to the general malformed-uuid response, if the node group with the given ID does not exist, the service returns a 404 Not Found response, as described in the errors documentation.

children-present
The service returns a 422 Unprocessable Entity and rejects the delete request if the node group that is being deleted has children.

The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;children-present&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Explains why the delete was rejected and names the children.</td>
</tr>
<tr>
<td>details</td>
<td>Contains the node group in question along with all of its children.</td>
</tr>
</tbody>
</table>

Related information
Node classifier errors on page 407
Familiarize yourself with error responses to make working the node classifier service API easier.

POST /v1/groups/<id>/pin
Use the /v1/groups/<id>/pin endpoint to pin nodes to the group with the given ID.

Request format
You can provide the names of the nodes to pin in two ways.

- As the value of the nodes query parameter. For multiple nodes, use a comma-separated list format.
  
  For example:

  POST /v1/groups/58463036-0efa-4365-b367-b5401c0711d3/pin?nodes=foo%2Cbar%2Cbaz

  This request pins the nodes foo, bar, and baz to the group.

- In the body of a request. In the nodes field of a JSON object, specify the node name as the value. For multiple nodes, use a JSON array.
  
  For example:

  {"nodes": ["foo", "bar", "baz"]}

  This request pins the nodes foo, bar, and baz to the group.

It's easier to use the query parameter method. However, if you want to affect a large number of nodes at once, the query string might get truncated. Strings are truncated if they exceed 8,000 characters. In such cases, use the second method. The request body in the second method is allowed to be many megabytes in size.

Response format
If the pin is successful, the service returns a 204 No Content response with an empty body.
**Error responses**

This endpoint uses the following error responses.

If you don't supply the `nodes` query parameter or a request body, the service returns a 400 Malformed Request response, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;missing-parameters&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Explains the missing <code>nodes</code> query parameter.</td>
</tr>
</tbody>
</table>

If you supply a request body that is not valid JSON, the service returns a 400 Malformed Request response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;malformed-request&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object with a body key containing the body as received by the service, and an error field containing a string describing the error encountered when trying to parse the request's body.</td>
</tr>
</tbody>
</table>

If the request's body is valid JSON, but the payload is not an object with just the `nodes` field and no other fields, the service returns a 400 Malformed Request response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;schema-violation&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Describes the difference between what was submitted and the required format.</td>
</tr>
</tbody>
</table>

**POST /v1/groups/<id>/unpin**

Use the `/v1/groups/<id>/unpin` endpoint to unpin nodes from the group with the given ID.

**Note:** Nodes not actually pinned to the group can be specified without resulting in an error.

**Request format**

You can provide the names of the nodes to pin in two ways.

- As the value of the `nodes` query parameter. For multiple nodes, use a comma-separated list format.
  
  For example:
  
  ```
  POST /v1/groups/58463036-0efa-4365-b367-b5401c0711d3/unpin?nodes=foo%2Cbar%2Cbaz
  ```
  
  This request unpins the nodes `foo`, `bar`, and `baz` from the group. If any of the specified nodes were not pinned to the group, they are ignored.

- In the body of a request. In the `nodes` field of a JSON object, specify the node name as the value. For multiple nodes, use a JSON array.
  
  For example:
  
  ```
  {"nodes": ["foo", "bar", "baz"]}
  ```
  
  This request unpins the nodes `foo`, `bar`, and `baz` from the group. If any of the specified nodes were not pinned to the group, they are ignored.
It's easier to use the query parameter method. However, if you want to affect a large number of nodes at once, the query string might get truncated. Strings are truncated if they exceed 8,000 characters. In such cases, use the second method. The request body in the second method is allowed to be many megabytes in size.

**Response format**

If the unpin is successful, the service returns a 204 *No Content* response with an empty body.

**Error responses**

If you don't supply the *nodes* query parameter or a request body, the service returns a 400 *Malformed Request* response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;missing-parameters&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Explains the missing <em>nodes</em> query parameter.</td>
</tr>
</tbody>
</table>

If a request body is supplied but it is not valid JSON, the service returns a 400 *Malformed Request* response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;malformed-request&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object with a <em>body</em> key containing the body as received by the service, and an <em>error</em> field containing a string describing the error encountered when trying to parse the request's body.</td>
</tr>
</tbody>
</table>

If the request's body is valid JSON, but the payload is not an object with just the *nodes* field and no other fields, the service returns a 400 *Malformed Request* response. The response object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;schema-violation&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Describes the difference between what was submitted and the required format.</td>
</tr>
</tbody>
</table>

**GET /v1/groups/:id/rules**

Use `/v1/groups/:id/rules` to resolve the rules for the requested group and then translate those rules to work with the nodes and inventory endpoints in PuppetDB.

**Response format**

A successful response includes these keys:

- **rule**
  - The rules for the group in classifier format.

- **rule_with_inherited**
  - The inherited rules (including the rules for this group) in classifier format

- **translated**
  - An object containing two children, each of the inherited rules translated into a different format.

  - **nodes_query_format**
    - The optimized translated inherited group in the format that works with the nodes endpoint in PuppetDB.

© 2020 Puppet, Inc.

**inventory_query_format**

The optimized translated inherited group in the format that works with the inventory endpoint in PuppetDB.

```json
{
  "rule": [
    "=",
    [
      "fact",
      "is_spaceship"
    ],
    "true"
  ],
  "rule_with_inherited": [
    "and",
    [
      "=",
      [
        "fact",
        "is_spaceship"
      ],
      "true"
    ],
    [
      "~",
      "name",
      ".*"
    ]
  ],
  "translated": {
    "nodes_query_format": [
      "or",
      [
        "=",

          "fact",
          "is_spaceship",
          true
        ]
      ]
    ],
    "inventory_query_format": [
      "or",
      [
        "=",
        "facts.is_spaceship",
        "true"
      ],
      [
        "=",
        "facts.is_spaceship",
        true
      ]
    ]
  }
}
```
Error responses
In addition to the general malformed-uuid error response, if the group with the given ID cannot be found, a 404 Not Found response is returned.

Related information
Error response description on page 407
Errors from the node classifier service are JSON responses.

Groups endpoint examples
Use example requests to better understand how to work with groups in the node classifier API.

These requests assume the following configuration:

- The Puppet master is running on puppetlabs-nc.example.vm with access to certificates and whitelisting to enable URL requests.
- Port 443 is open.

Create a group called My Nodes
This request uses POST /v1/groups to create a group called My Nodes.

Bash

type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups"
data='{"name": "My Nodes",
"parent": "00000000-0000-4000-8000-000000000000",
"environment": "production",
"classes": {}}'
curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key"
--request POST "$uri" --data "$data"

Related information
POST /v1/groups on page 365
Use the /v1/groups endpoint to create a new node group without specifying its ID. When you use this endpoint, the node classifier service randomly generates an ID.

Get the group ID of My Nodes
This request uses the groups endpoint to get details about groups.

Bash

cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups"
curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key"
"$uri"

The response is a JSON file containing details about all groups, including the My Nodes group ID.

{
"environment_trumps": false,

Groups endpoint on page 361
The groups endpoint is used to create, read, update, and delete groups.

Pin a node to the My Nodes group
This request uses POST /v1/groups/<id> to pin the node example-to-pin.example.vm to My Groups using the group ID retrieved in the previous step.

Bash

type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups/085e2797-32f3-4920-9412-8e9decf4ef65/pin"
data='{ "nodes": ["example-to-pin.example.vm"] }'
curl --header "$type_header" --header "$auth_header" --request POST "$uri" --data "$data"

Related information
POST /v1/groups/<id> on page 372
Use the /v1/groups/<id> endpoint to update the name, environment, parent, rule, classes, class parameters, configuration data, and variables of the node group with the given ID by submitting a node group delta.

Pin a second node to the My Nodes group
This request uses POST /v1/groups/<id> to pin a second node example-to-pin-2.example.vm to My Groups.

Note: You must supply all the nodes to pin to the group. For example, this request includes both example-to-pin.example.vm and example-to-pin-2.example.vm.

Bash

type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups/085e2797-32f3-4920-9412-8e9decf4ef65/pin"
data='{ "nodes": ["example-to-pin.example.vm", "example-to-pin-2.example.vm"] }'
curl --insecure --header "$type_header" --header "$auth_header" --request POST "$uri" --data "$data"

Related information
POST /v1/groups/<id> on page 372
Use the `/v1/groups/<id>` endpoint to update the name, environment, parent, rule, classes, class parameters, configuration data, and variables of the node group with the given ID by submitting a node group delta.

**Unpin a node from the My Nodes group**
This request uses POST `/v1/groups/<id>` to unpin the node `example-to-unpin.example.vm` from `My Groups`.

```
Bash

type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups/a02ee4a7-8ec1-44ec-99a6-ef362596fd6e/unpin"
data='{ "nodes": ["example-to-unpin"] }'

curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key"
--request POST "$uri" --data "$data"
```

**Add a class and parameters to the My Nodes group**
This request uses POST `/v1/groups/<id>` to specify the `apache` class and parameters for `My Groups`.

```
Bash

type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/classifier-api/v1/groups/085e2797-32f3-4920-9412-8e9decf4ef65"
data='{"classes":
    {"apache":
        {"serveradmin": "bob@example.com",
        "keepalive_timeout": null}
    }
}

curl --insecure --header "$type_header" --header "$auth_header" --request
POST "$uri" --data "$data"
```

**Related information**
POST `/v1/groups/<id>` on page 372
Use the `/v1/groups/<id>` endpoint to update the name, environment, parent, rule, classes, class parameters, configuration data, and variables of the node group with the given ID by submitting a node group delta.

**Classes endpoint**
Use the `classes` endpoints to retrieve lists of classes, including classes with specific environments. The output from this endpoint is especially useful for creating new node groups, which usually contain a reference to one or more classes.

The node classifier gets its information about classes from Puppet, so don't use this endpoint to create, update, or delete classes.

**GET /v1/classes**
Use the `/v1/classes` endpoint to retrieve a list of all classes known to the node classifier.

**Note:** All other operations on classes require using the environment-specific endpoints.

All `/classes` endpoints return the classes *currently known* to the node classifier, which retrieves them periodically from the master. To force an update, use the `update_classes` endpoint. To determine when classes were last retrieved from the master, use the `last_class_update` endpoint.

© 2020 Puppet, Inc.
Response format

The response is a JSON array of class objects. Each class object contains these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the class (a string).</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the environment that this class exists in. Note that the same class can exist in different environments and can have different parameters in each environment.</td>
</tr>
<tr>
<td>parameters</td>
<td>An object describing the parameters and default parameter values for the class. The keys of this object are the parameter names (strings). Each value is the default value for the associated parameter as a string, boolean, number, structured value, or null. If the value is null, the parameter is required.</td>
</tr>
</tbody>
</table>

This is an example of a class object:

```
{
    "name": "apache",
    "environment": "production",
    "parameters": {
        "default_mods": true,
        "default_vhost": true,
        ...
    }
}
```

GET /v1/environments/<environment>/classes

Use the /v1/environments/<environment>/classes to retrieve a list of all classes known to the node classifier within the given environment.

Response format

The response is a JSON array of class objects. Each class object contains these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the class (a string).</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the environment that this class exists in. Note that the same class can exist in different environments and can have different parameters in each environment.</td>
</tr>
<tr>
<td>parameters</td>
<td>An object describing the parameters and default parameter values for the class. The keys of this object are the parameter names (strings). Each value is the default value for the associated parameter as a string, boolean, number, structured value, or null. If the value is null, the parameter is required.</td>
</tr>
</tbody>
</table>
Error responses
This request does not produce error responses.

GET /v1/environments/<environment>/classes/<name>
Use the /v1/environments/\<environment\>/classes/\<name\> endpoint to retrieve the class with the given name in the given environment.

Response format
If the class exists, the response is a JSON array of class objects. Each class object contains these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the class (a string).</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the environment that this class exists in. Note that the same class can exist in different environments and can have different parameters in each environment.</td>
</tr>
<tr>
<td>parameters</td>
<td>An object describing the parameters and default parameter values for the class. The keys of this object are the parameter names (strings). Each value is the default value for the associated parameter as a string, boolean, number, structured value, or null. If the value is null, the parameter is required.</td>
</tr>
</tbody>
</table>

Error responses
If the class with the given name cannot be found, the service returns a 404 Not Found response with an empty body.

Classification endpoint
The classification endpoint takes a node name and a set of facts, and returns information about how that node is classified. The output can help you test your classification rules.

POST /v1/classified/nodes/<name>
Use the /v1/classified/nodes/\<name\> endpoint to retrieve the classification information for the node with the given name and facts as supplied in the body of the request.

Request format
The request body can contain a JSON object describing the facts and trusted facts of the node to be classified. The object can have these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>fact</td>
<td>The regular, non-trusted facts of the node. The value of this key is a further object, whose keys are fact names, and whose values are the fact values. Fact values can be a string, number, boolean, array, or object.</td>
</tr>
<tr>
<td>trusted</td>
<td>The trusted facts of the node. The values of this key are subject to the same restrictions as those on the value of the fact key.</td>
</tr>
</tbody>
</table>
Response format

The response is a JSON object describing the node post-classification, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node (a string).</td>
</tr>
<tr>
<td>groups</td>
<td>An array of the group-ids (strings) that this node was classified into.</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the environment that this node uses, which is taken from the node groups the node was classified into.</td>
</tr>
<tr>
<td>classes</td>
<td>An object where the keys are class names and the values are objects that map parameter names to values.</td>
</tr>
<tr>
<td>parameters</td>
<td>An object where the keys are top-level variable names and the values are the values assigned to those variables.</td>
</tr>
</tbody>
</table>

This is an example of a response from this endpoint:

```json
{
   "name": "foo.example.com",
   "groups": ["9c0c7d07-a199-48b7-9999-3cdf7654e0bf", "96d1a058-225d-48e2-a1a8-80819d31751d"],
   "environment": "staging",
   "parameters": {},
   "classes": {
      "apache": {
         "keepalive_timeout": 30,
         "log_level": "notice"
      }
   }
}
```

Error responses

If the node is classified into multiple node groups that define conflicting classifications for the node, the service returns a 500 Server Error response.

The body of this response contains the usual JSON error object described in the errors documentation.

The `kind` key of the error is "classification-conflict", the `msg` describes generally why this happens, and the `details` key contains an object that describes the specific conflicts encountered.

The details object can have these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>Maps directly to an array of value detail objects (described below).</td>
</tr>
<tr>
<td>variables</td>
<td>Contains an object with a key for each conflicting variable, whose values are an array of value detail objects.</td>
</tr>
<tr>
<td>classes</td>
<td>Contains an object with a key for each class that had conflicting parameter definitions, whose values are further objects that describe the conflicts for that class's parameters.</td>
</tr>
</tbody>
</table>
A value details object describes one of the conflicting values defined for the environment, a variable, or a class parameter. Each object contains these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The defined value, which is a string for environment and class parameters, but for a variable can be any JSON value.</td>
</tr>
<tr>
<td>from</td>
<td>The node group that the node was classified into that caused this value to be added to the node's classification. This group cannot define the value, because it can be inherited from an ancestor of this group.</td>
</tr>
<tr>
<td>defined_by</td>
<td>The node group that actually defined this value. This is often the <code>from</code> group, but could instead be an ancestor of that group.</td>
</tr>
</tbody>
</table>

This example shows a classification conflict error object with node groups truncated for clarity:

```json
{
  "kind": "classification-conflict",
  "msg": "The node was classified into multiple unrelated node groups that defined conflicting class parameters or top-level variables. See `details` for a list of the specific conflicts.",
  "details": {
    "classes": {
      "songColors": {
        "blue": [
          {
            "value": "Blue Suede Shoes",
            "from": {
              "name": "Elvis Presley",
              "classes": {},
              "rule": ["=","nodename","the-node"],
              ...
            },
            "defined_by": {
              "name": "Carl Perkins",
              "classes": {"songColors": {"blue": "Blue Suede Shoes"}},
              "rule": ["not", ["=","nodename","the-node"],
              ...
            }
          },
          {
            "value": "Since You've Been Gone",
            "from": {
              "name": "Aretha Franklin",
              "classes": {"songColors": {"blue": "Since You've Been Gone"}},
              ...
            },
            "defined_by": {
              "name": "Aretha Franklin",
              "classes": {"songColors": {"blue": "Since You've Been Gone"}},
              ...
            }
          }
        ]
      }
    }
  }
}
```
In this example, the conflicting "Blue Suede Shoes" value was included in the classification because the node matched the "Elvis Presley" node group (because that is the value of the "from" key), but that node group doesn't define the "Blue Suede Shoes" value. That value is defined by the "Carl Perkins" node group, which is an ancestor of the "Elvis Presley" node group, causing the latter to inherit the value from the former. The other conflicting value, "Since You've Been Gone", is defined by the same node group that the node matched.

**Related information**

Node classifier errors on page 407

Familiarize yourself with error responses to make working the node classifier service API easier.

**POST /v1/classified/nodes/<name>/explanation**

Use the `/v1/classified/nodes/\<name\>/explanation` endpoint to retrieve an explanation of how a node is classified by submitting its facts.

**Request format**

The body of the request must be a JSON object describing the node's facts. This object uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>fact</td>
<td>Describes the regular (non-trusted) facts of the node. Its value must be a</td>
</tr>
<tr>
<td></td>
<td>further object whose keys are fact names, and whose values are the</td>
</tr>
<tr>
<td></td>
<td>corresponding fact values. Structured facts can be included here; structured</td>
</tr>
<tr>
<td></td>
<td>fact values are further objects or arrays.</td>
</tr>
<tr>
<td>trusted</td>
<td>Optional key that describes the trusted facts of the node. Its value</td>
</tr>
<tr>
<td></td>
<td>has exactly the same format as the <code>fact</code> key's value.</td>
</tr>
<tr>
<td>name</td>
<td>The node's name from the request's URL is merged into this object under</td>
</tr>
<tr>
<td></td>
<td>this key.</td>
</tr>
</tbody>
</table>

This is an example of a valid request body:

```json
{
  "fact": {
    "ear-tips": "pointed",
    "eyebrow pitch": "40",
    "hair": "dark",
    "resting bpm": "120",
    "blood oxygen transporter": "hemocyanin",
    "anterior tricuspsids": "2",
    "appendices": "1",
    "spunk": "10"
  }
}
```

**Response format**

The response is a JSON object that describes how the node would be classified.

- If the node would be successfully classified, this object contains the final classification.
- If the classification would fail due to conflicts, this object contains a description of the conflicts.

This response is intended to provide insight into the entire classification process, so that if a node isn't classified as expected, you can trace the deviation.

Classification proceeds in this order:
1. All node group rules are tested on the node's facts and name, and groups that don't match the node are culled, leaving the matching groups.

2. Inheritance relations are used to further cull the matching groups, by removing any matching node group that has a descendant that is also a matching node group. Those node groups that are left over are leaf groups.

3. Each leaf group is transformed into its inherited classification by adding all the inherited values from its ancestors.

4. All of the inherited classifications and individual node classifications are inspected for conflicts. A conflict occurs whenever two inherited classifications define different values for the environment, a class parameter, or a top-level variable.

5. Any individual node classification, including classes, class parameters, configuration data, and variables, is added.

6. Individual node classification is applied to the group classification, forming the final classification, which is then returned to the client.

The JSON object returned by this endpoint uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>match_explanations</td>
<td>Corresponds to step 1 of classification, finding the matching node groups. This key’s value is an explanation object just like those found in node check-ins, which maps between a matching group’s ID and an explained condition object that demonstrates why the node matched that group’s rule.</td>
</tr>
<tr>
<td>leaf_groups</td>
<td>Corresponds to step 2 of classification, finding the leaves. This key’s value is an array of the leaf groups (that is, those groups that are not related to any of the other matching groups).</td>
</tr>
<tr>
<td>inherited_classifications</td>
<td>Corresponds to step 3 of classification, adding inherited values. This key’s value is an object mapping from a leaf group’s ID to the classification values provided by that group (after inheritance).</td>
</tr>
<tr>
<td>conflicts</td>
<td>Corresponds to step 4 of classification. This key is present only if there are conflicts between the inherited classifications. Its value is similar to a classification object, but wherever there was a conflict there’s an array of conflict details instead of a single classification value. Each of these details is an object with three keys: value, from, and defined_by. The value key is a conflicting value, the from key is the group whose inherited classification provided this value, and the defined_by key is the group that actually defined the value (which can be an ancestor of the from group).</td>
</tr>
<tr>
<td>individual_classification</td>
<td>Corresponds to step 5 of classification. Its value includes classes, class parameters, configuration data, and variables applied directly during this stage.</td>
</tr>
<tr>
<td>final_classification</td>
<td>Corresponds to step 6 of classification, present only if there are no conflicts between the inherited classifications. Its value is the result of merging all individual node classification and group classification.</td>
</tr>
<tr>
<td>node_as_received</td>
<td>The submitted node object as received by the service, after adding the name and, if not supplied by the client, an empty trusted object. This key does not correspond to any of the classification steps.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>classification_source</td>
<td>An annotated version of the classification that has the environment and every class parameter and variable replaced with an &quot;annotated value&quot; object. This key does not correspond to any of the classification steps.</td>
</tr>
</tbody>
</table>

This example shows a response the endpoint could return in the case of a successful classification:

```json
{
    "node_as_received": {
        "name": "Tuvok",
        "trusted": {},
        "fact": {
            "ear-tips": "pointed",
            "eyebrow pitch": "30",
            "blood oxygen transporter": "hemocyanin",
            "anterior tricusps": "2",
            "hair": "dark",
            "resting bpm": "200",
            "appendices": "0",
            "spunk": "0"
        }
    },
    "match_explanations": {

      ["=",
        ["fact", "blood oxygen transporter"], "hemocyanin"
      ]
    ],
    "25"
  }
}
```
Commands endpoint

Use the commands endpoint to unpin specified nodes from all groups they’re pinned to.

**POST /v1/commands/unpin-from-all**

Use the /v1/commands/unpin-from-all to unpin specified nodes from all groups they’re pinned to. Nodes that are dynamically classified using rules aren't affected.

Nodes are unpinned from only those groups for which you have view and edit permissions. Because group permissions are applied hierarchically, you must have Create, edit, and delete child groups or Edit child group rules permissions for the parent groups of the groups you want to unpin the node from.

**Note:** As number of groups increases, response time can increase significantly with the unpin-from-all endpoint.

**Request format**

The request body must be a JSON object describing the nodes to unpin, using the following key:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodes</td>
<td>The certname of the nodes (required).</td>
</tr>
</tbody>
</table>
pe | Managing nodes | 393

For example:
{"nodes": ["foo", "bar"]}
Response format
If unpinning is successful, the service returns a list of nodes with the groups they were unpinned from. If a node
wasn't pinned to any groups, it's not included in the response.
{"nodes": [{"name": "foo",
"groups": [{"id": "8310b045-c244-4008-88d0-b49573c84d2d",
"name": "Webservers",
"environment": "production"},
{"id": "84b19b51-6db5-4897-9409-a4a3a94b7f09",
"name": "Test",
"environment": "test"}]},
{"name": "bar",
"groups": [{"id": "84b19b51-6db5-4897-9409-a4a3a94b7f09",
"name": "Test",
"environment": "test"}]}]}
Assuming token is set as an environment variable, the example below unpins "host1.example" and "host2.example":
Bash
type_header= 'Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):4433/classifier-api/v1/commands/
unpin-from-all"
data='{"nodes": ["host1.example", "host2.example"]}'
curl --insecure --header "$type_header"
POST "$uri" --data "$data"

--header "$auth_header"--request

The classifier responds with information about each group it is removed from:
{"nodes":
[{"name":"host1.example","groups":[{"id":"2d83d860-19b4-4f7b-8b70e5ee4d8646db","name":"test","environment":"production"}]},
{"name":"host2.example","groups":[{"id":"2d83d860-19b4-4f7b-8b70e5ee4d8646db","name":"test","environment":"production"}]}]}

Environments endpoint
Use the environments endpoint to retrieve information about environments in the node classifier. The output tells
you either which environments are available or whether a named environment exists. The output can be helpful when
creating new node groups, which must be associated with an environment. The node classifier gets its information
about environments from Puppet, so do not use this endpoint to create, update, or delete them.
GET /v1/environments
Use the /v1/environments endpoint to retrieve a list of all environments known to the node classifier.
Response format
The response is a JSON array of environment objects, using the following keys:
Key

Definition

name

The name of the environment (a string).

© 2020 Puppet, Inc.


<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>sync_succeeded</td>
<td>Whether the environment synched successfully during the last class synchronization (a Boolean).</td>
</tr>
</tbody>
</table>

**Error responses**

No error responses specific to this request are expected.

**GET /v1/environments/<name>**

Use the `/v1/environments/\<name\>` endpoint to retrieve the environment with the given name. The main use of this endpoint is to check if an environment actually exists.

**Response format**

If the environment exists, the service returns a 200 response with an environment object in JSON format.

**Error responses**

If the environment with the given name cannot be found, the service returns a 404: `Not Found` response with an empty body.

**PUT /v1/environments/<name>**

Use the `/v1/environments/\<name\>` endpoint to create a new environment with the given name.

**Request format**

No further information is required in the request besides the `name` portion of the URL.

**Response format**

If the environment is created successfully, the service returns a 201: `Created` response whose body is the environment object in JSON format.

**Error responses**

No error responses specific to this operation are expected.

**Nodes check-in history endpoint**

Use the `nodes` endpoint to retrieve historical information about nodes that have checked into the node classifier.

**Enable check-in storage to use this endpoint**

Node check-in storage is disabled by default because it can place excessive loads on larger deployments. You must enable node check-in storage before using the check-in history endpoint. If node check-in storage is not enabled, the endpoint returns an empty array.

To enable node check-in storage, set the `classifier_node_check_in_storage` parameter in the `puppet_enterprise::profile::console` class to `true`.

**Related information**

Set configuration data on page 152
Configuration data set in the console is used for automatic parameter lookup, the same way that Hiera data is used. Console configuration data takes precedence over Hiera data, but you can combine data from both sources to configure nodes.

GET /v1/nodes

Use the /v1/nodes endpoint to retrieve a list of all nodes that have checked in with the node classifier, each with their check-in history.

Query Parameters

limit

Controls the maximum number of nodes returned. limit=10 returns 10 nodes.

offset

Specifies how many nodes to skip before the first returned node. offset=20 skips the first 20 nodes.

CAUTION: In deployments with large numbers of nodes, a large or unspecified limit might cause the console-services process to run out of memory and crash.

Response format

The response is a JSON array of node objects. Each node object contains these two keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node according to Puppet (a string).</td>
</tr>
<tr>
<td>check_ins</td>
<td>An array of check-in objects (described below).</td>
</tr>
</tbody>
</table>

Each check-in object describes a single check-in of the node. The check-in objects have the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>The time of the check-in as a string in ISO 8601 format (with timezone).</td>
</tr>
<tr>
<td>explanation</td>
<td>An object mapping between IDs of groups that the node was classified into and explained condition objects that describe why the node matched this group's rule.</td>
</tr>
<tr>
<td>transaction_uuid</td>
<td>A uuid representing a particular Puppet transaction that is submitted by Puppet at classification time. This makes it possible to identify the check-in involved in generating a specific catalog and report.</td>
</tr>
</tbody>
</table>

The explained condition objects are the node group's rule condition marked up with the node's value and the result of evaluation. Each form in the rule (that is, each array in the JSON representation of the rule condition) is replaced with an object that has two keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>A Boolean that is the result of evaluating this form. At the top level, this is the result of the entire rule condition, but because each sub-condition is marked up with its value, you can use this to understand, say, which parts of an or condition were true.</td>
</tr>
<tr>
<td>form</td>
<td>The condition form, with all sub-forms as further explained condition objects.</td>
</tr>
</tbody>
</table>
Besides the condition markup, the comparison operations of the rule condition have their first argument (the fact path) replaced with an object that has both the fact path and the value that was found in the node at that path.

The following example shows the format of an explained condition.

Start with a node group with the following rule:

```json
["and", ["\">=", ["fact", "pressure hulls"], "1"],
  ["\"=", ["fact", "warp cores"], "0"],
  ["\">=", ["fact", "docking ports"], "10"]
```

The following node checks into the classifier:

```json
{
  "name": "Deep Space 9",
  "fact": {
    "pressure hulls": "10",
    "docking ports": "18",
    "docking pylons": "3",
    "warp cores": "0",
    "bars": "1"
  }
}
```

When the node checks in for classification, it matches the above rule, so that check-in's explanation object has an entry for the node group that the rule came from. The value of this entry is this explained condition object:

```json
{
  "value": true,
  "form": [
    "and",
    {
      "value": true,
      "form": ["\">=", "fact", "pressure hulls"], "value": "3"],
    "1"
  },
  {
    "value": true,
    "form": ["\"=", "fact", "warp cores"], "value": "0"], "0"
  },
  {
    "value": true,
    "form": ["\">", "fact", "docking ports"], "value": "18"], "19"
  }
}
```

**GET /v1/nodes/<node>**

Use the /v1/nodes/<node> endpoint to retrieve the check-in history for only the specified node.

**Response format**

The response is one node object as described above in the GET /v1/nodes documentation, for the specified node. The following example shows a node object:

```json
{
  "name": "Deep Space 9",
  "check_ins": [
    { "time": "2369-01-04T03:00:00Z",
      "explanation": {
```
"53029cf7-2070-4539-87f5-9fc754a0f041": {
  "value": true,
  "form": [
    "and",
    {
      "value": true,
      "form": [">=", {"path": ["fact", "pressure hulls"], "value": "3"}, "1"]
    },
    {
      "value": true,
      "form": ["=", {"path": ["fact", "warp cores"], "value": "0"}, "0"]
    },
    {
      "value": true,
      "form": [">" {"path": ["fact", "docking ports"], "value": "18"}, "9"]
    }
  ]
},
"transaction_uuid": "d3653a4a-4bee-426e-a04d-dbebec00e97f"
}

Error responses

If the specified node has not checked in, the service returns a 404: Not Found response, with the usual JSON error response in its body.

Group children endpoint

Use the group children endpoint to retrieve a specified group and its descendents.

GET /v1/group-children/:id

Use the /v1/group-children/:id endpoint to retrieve a specified group and its descendents.

Request format

The request body must be a JSON object specifying a group and an optional depth indicating how many levels of descendents to return.

- depth: (optional) an integer greater than or equal to 0 that limits the depth of trees returned. Zero means return the group with no children.

For example:

GET /v1/group-children/00000000-0000-4000-8000-000000000000?depth=2

Response format

The response is a JSON array of group objects, using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node group (a string).</td>
</tr>
<tr>
<td>id</td>
<td>The node group's ID, which is a string containing a type-4 (random) UUID.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>description</td>
<td>An optional key containing an arbitrary string describing the node group.</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the node group’s environment (a string), which indirectly defines what classes are available for the node group to set, and is the environment that nodes classified into this node group run under.</td>
</tr>
<tr>
<td>environment_trumps</td>
<td>This is a boolean that changes the behavior of classifications that this node group is involved in. The default behavior is to return a classification-conflict error if the node groups that a node is classified into do not all have the same environment. If this flag is set, then this node group’s environment overrides the environments of the other node groups (provided that none of them also have this flag set), with no attempt made to validate that the other node groups’ classes and class parameters exist in this node group’s environment.</td>
</tr>
<tr>
<td>parent</td>
<td>The ID of the node group’s parent (a string). A node group is not permitted to be its own parent, unless it is the All Nodes group (which is the root of the hierarchy). Note that the root group always has the lowest-possible random UUID, 00000000-0000-4000-8000-000000000000.</td>
</tr>
<tr>
<td>rule</td>
<td>A boolean condition on node properties. When a node's properties satisfy this condition, it's classified into the node group. See Rule condition grammar for more information on how this condition must be structured.</td>
</tr>
<tr>
<td>classes</td>
<td>An object that defines both the classes consumed by nodes in this node group and any non-default values for their parameters. The keys of the object are the class names, and the values are objects describing the parameters. The parameter objects’ keys are parameter names, and the values are what the node group sets for that parameter (always a string).</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>deleted</td>
<td>An object similar the classes object that shows which classes and class parameters set by the node group have since been deleted from Puppet. If none of the node group's classes or parameters have been deleted, this key is not present, so checking the presence of this key is an easy way to check whether the node group has references that need updating. The keys of this object are class names, and the values are further objects. These secondary objects always contain the puppetlabs.classifier/deleted key, whose value is a Boolean indicating whether the entire class has been deleted from Puppet. The other keys of these objects are parameter names, and the other values are objects that always contain two keys: puppetlabs.classifier/deleted, mapping to a boolean indicating whether the specific class parameter has been deleted from Puppet; and value, mapping to the string value set by the node group for this parameter (the value is duplicated for convenience, as it also appears in the classes object).</td>
</tr>
<tr>
<td>variables</td>
<td>An object that defines the values of any top-level variables set by the node group. The object is a mapping between variable names and their values (which can be any JSON value).</td>
</tr>
<tr>
<td>children</td>
<td>A JSON array of the group's immediate children. Children of children are included to the optionally-specified depth.</td>
</tr>
<tr>
<td>immediate_child_count</td>
<td>The number of immediate children of the group. Child count reflects the number of children that exist in the classifier, not the number that are returned in the request, which can vary based on permissions and query parameters.</td>
</tr>
</tbody>
</table>

The following is an example response from a query of the root node group with two children, each with three children. The user has permission to view only child-1 and grandchild-5, which limits the response.

```json
[
  {
    "name": "child-1",
    "id": "652227cd-af24-4fd8-96d4-b9b55ca28efb",
    "parent": "00000000-0000-4000-8000-000000000000",
    "environment_trumps": false,
    "rule": ["and", ["=" , ["fact", "foo"] , "bar"] , ["not", ["<", ["fact", "uptime_days"] , 31"] ] ] ,
    "variables": {},
    "environment": "test",
    "classes": {},
    "children": [ {
      "name": "grandchild-1",
      "id": "a3d976ad-51d3-4a29-af57-09990f3a2481",
      "parent": "652227cd-af24-4fd8-96d4-b9b55ca28efb",
      "environment_trumps": false,
```
"rule": ["and", ["="", ["fact", "foo"], "bar"], ["or", ["~", "name", "db"], ["<", ["fact", "processorcount"], "9"], ["="", ["fact", "operatingsystem"], "Ubuntu"]],
  "variables": {},
  "environment": "test",
  "classes": {},
  "children": [],
  "immediate_child_count": 0
},

{ "name": "grandchild-2",
  "id": "71905c11-5295-41cf-a143-31b278cfc859",
  "parent": "652227cd-af24-4fd8-96d4-b9b55ca28efb",
  "environment_trumps": false,
  "rule": ["and", ["="", ["fact", "foo"], "bar"], ["not", ["~", ["fact", "kernel"], "SunOS"]],
  "variables": {},
  "environment": "test",
  "classes": {},
  "children": [],
  "immediate_child_count": 0
}
},
"immediate_child_count": 2
},

{ "name": "grandchild-5",
  "id": "0bb94f26-2955-4adc-8460-f5ce244d5118",
  "parent": "0960f75e-cdd0-4966-96f6-5e60948a7217",
  "environment_trumps": false,
  "rule": ["and", ["="", ["fact", "foo"], "bar"], ["and", ["<", ["fact", "processorcount"], "16"], [">="", ["fact", "kernelmajversion"], "2"]],
  "variables": {},
  "environment": "test",
  "classes": {},
  "children": [],
  "immediate_child_count": 0
}
]

**Permissions**

The response returned varies based on your permissions.

<table>
<thead>
<tr>
<th>Permissions</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>View the specified group only</td>
<td>An array containing the group and its descendents, ending at the optional depth</td>
</tr>
<tr>
<td>View descendents of the specified group, but not the group itself</td>
<td>An array starting at the roots of every tree you have permission to view and ending at the optional depth</td>
</tr>
<tr>
<td>View neither the specified group nor its descendents</td>
<td>An empty array</td>
</tr>
</tbody>
</table>

**Error responses**

Responses and keys returned for group requests depend on the type of error.

**malformed-uuid**
If the requested ID is not a valid UUID, the service returns a 400: Bad Request response using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;malformed-uuid&quot;</td>
</tr>
<tr>
<td>details</td>
<td>The malformed UUID as received by the server.</td>
</tr>
</tbody>
</table>

**malformed-number or illegal-count**

If the value of the depth parameter is not an integer, or is a negative integer, the service returns a 400: Bad Request response using one of the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;malformed-number&quot; or &quot;illegal-count&quot;</td>
</tr>
</tbody>
</table>

**Rules endpoint**

Use the rules endpoint to translate a group's rule condition into PuppetDB query syntax.

**POST /v1/rules/translate**

Translate a group's rule condition into PuppetDB query syntax.

**Request format**

The request's body contains a rule condition as it would appear in the rule field of a group object.

The endpoint supports an optional query parameter format, which defaults to `nodes`. If specified as `?format=inventory`, it allows you to get the classifier rules in a compatible dot notation format instead of the standard PuppetDB AST.

**Response format**

The response is a PuppetDB query string that can be used with PuppetDB nodes endpoint in order to see which nodes would satisfy the rule condition (that is, which nodes would be classified into a group with that rule).

**Error responses**

Rules that use structured or trusted facts cannot be converted into PuppetDB queries, because PuppetDB does not yet support structured or trusted facts. If the rule cannot be translated into a PuppetDB query, the server returns a 422 Unprocessable Entity response containing the usual JSON error object. The error object has a kind of "untranslatable-rule", a msg that describes why the rule cannot be translated, and contains the received rule in details.

If the request does not contain a valid rule, the server returns a 400 Bad Request response with the usual JSON error object. If the rule was not valid JSON, the error's kind is "malformed-request", the msg states that the request's body could not be parsed as JSON, and the details contain the request's body as received by the server.

If the rule does not conform to the rule grammar, the kind key is "schema-violation", and the details key is an object with submitted, schema, and error keys which respectively describe the submitted object, the schema that object is expected to conform to, and how the submitted object failed to conform to the schema.

**Related information**

GET /v1/groups on page 361

© 2020 Puppet, Inc.
Use the /v1/groups endpoint to retrieve a list of all node groups in the node classifier.

**Import hierarchy endpoint**

Use the import hierarchy endpoint to delete all existing node groups from the node classifier service and replace them with the node groups in the body of the submitted request.

**POST /v1/import-hierarchy**
Delete all existing node groups from the node classifier service and replace them with the node groups in the body of the submitted request.

The request’s body must contain an array of node groups that form a valid and complete node group hierarchy. Valid means that the hierarchy does not contain any cycles, and complete means that every node group in the hierarchy is reachable from the root.

**Request format**

The request body must be a JSON array of node group objects as described in the groups endpoint documentation. All fields of the node group objects must be defined; no default values are supplied by the service.

Note that the output of the group collection endpoint, /v1/groups, is valid input for this endpoint.

**Response format**

If the submitted node groups form a complete and valid hierarchy, and the replacement operation is successful, a 204 No Content response with an empty body is returned.

**Error responses**

If any of the node groups in the array are malformed, a 400 Bad Request response is returned. The response contains the usual JSON error payload. The kind key is "schema-violation"; the msg key contains a short description of the problems with the malformed node groups; and the details key contains an object with three keys:

- **submitted**: an array of only the malformed node groups found in the submitted request.
- **error**: an array of structured descriptions of how the node group at the corresponding index in the submitted array failed to meet the schema.
- **schema**: the structured schema for node group objects.

If the hierarchy formed by the node groups contains a cycle, then a 422 Unprocessable Entity response is returned. The response contains the usual JSON error payload, where the kind key is "inheritance-cycle", the msg key contains the names of the node groups in the cycle, and the details key contains an array of the complete node group objects in the cycle.

If the hierarchy formed by the node groups contains node groups that are unreachable from the root, then a 422 Unprocessable Entity response is returned. The response contains the usual JSON error payload, where the kind key is "unreachable-groups", the msg lists the names of the unreachable node groups, and the details key contains an array of the unreachable node group objects.

**Related information**

Groups endpoint on page 361
The groups endpoint is used to create, read, update, and delete groups.

Node classifier errors on page 407
Familiarize yourself with error responses to make working the node classifier service API easier.

**Last class update endpoint**

Use the last class update endpoint to retrieve the time that classes were last updated from the Puppet master.

**GET /v1/last-class-update**

Use the /v1/last-class-update endpoint to retrieve the time that classes were last updated from the Puppet master.

**Response**

The response is always an object with one field, last_update. If there has been an update, the value of last_update field is the time of the last update in ISO8601 format. If the node classifier has never updated from Puppet, the field is null.

**Update classes endpoint**

Use update classes endpoint to trigger the node classifier to update class and environment definitions from the Puppet master.

**POST /v1/update-classes**

Use the /v1/update-classes endpoint to trigger the node classifier to update class and environment definitions from the Puppet master. The classifier service uses this endpoint when you refresh classes in the console.

**Note:** If you don’t use Code Manager and you changed the default value of the environment-class-cache-enabled server setting, you must manually delete the environment cache before using this endpoint.

**Query parameters**

The request accepts the following optional parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>If provided, fetches classes for only the specified environment.</td>
</tr>
</tbody>
</table>

For example:

**Bash**

```bash
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):4433/classifier-api/v1/update-classes?environment=production"

curl --cert "$cert" --cacert "$cacert" --key "$key" --request POST "$uri"
```

**Response**

For a successful update, the service returns a 201 response with an empty body.

**Error responses**

If the Puppet master returns an unexpected status to the node classifier, the service returns a 500: Server Error response with the following keys:
**Key** | **Definition**
---|---
kind | "unexpected-response"
msg | Describes the error
details | A JSON object, which has url, status, headers, and body keys describing the response the classifier received from the Puppet master

**Related information**

Enable or disable cached data when updating classes on page 155

The optional environment-class-cache-enabled setting specifies whether cached data is used when updating classes in the console. When true, Puppet Server refreshes classes using file sync, improving performance.

**Validation endpoints**

Use validation endpoints to validate groups in the node classifier.

**POST /v1/validate/group**

Use the /v1/validate/group endpoint to validate groups in the node classifier.

**Request format**

The request contains a group object. The request uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node group (required).</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the node group's environment. This key is optional; if it's not provided, the default environment (production) is used.</td>
</tr>
<tr>
<td>environment_trumps</td>
<td>Whether this node group's environment overrides those of other node groups at classification-time. This key is optional; if it's not provided, the default value of false is used.</td>
</tr>
<tr>
<td>description</td>
<td>A string describing the node group. This key is optional; if it's not provided, the node group has no description and this key doesn't appear in responses.</td>
</tr>
<tr>
<td>parent</td>
<td>The ID of the node group's parent (required).</td>
</tr>
<tr>
<td>rule</td>
<td>The condition that must be satisfied for a node to be classified into this node group. The structure of this condition is described in the &quot;Rule Condition Grammar&quot; section above.</td>
</tr>
<tr>
<td>variables</td>
<td>An object that defines the names and values of any top-level variables set by the node group. The keys of the object are the variable names, and the corresponding value is that variable's value, which can be any sort of JSON value. The variables key is optional, and if a node group does not define any top-level variables then it can be omitted.</td>
</tr>
</tbody>
</table>
### classes

An object that defines the classes to be used by nodes in the node group. The **classes** key is required, and at minimum is an empty object (`). The **classes** key also contains the parameters for each class. Some classes have required parameters. This is a two-level object; that is, the keys of the object are class names (strings), and each key's value is another object that defines class parameter values. This innermost object maps between class parameter names and their values. The keys are the parameter names (strings), and each value is the parameter's value, which can be any kind of JSON value. The **classes** key is not optional; if it is missing, the service returns a **400: Bad Request** response.

### Response format

If the group is valid, the service returns a **200 OK** response with the validated group as the body.

If a validation error is encountered, the service returns one of the following **400**-level error responses.

#### Responses and keys returned for create group requests depend on the type of error.

**schema-violation**

If any of the required keys are missing or the values of any of the defined keys do not match the required type, the service returns a **400: Bad Request** response using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;schema-violation&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains three keys:</td>
</tr>
<tr>
<td></td>
<td>• <code>code&gt;submitted&lt;/code&gt;</code>: Describes the submitted object.</td>
</tr>
<tr>
<td></td>
<td>• <code>schema</code>: Describes the schema that object is expected to conform to.</td>
</tr>
<tr>
<td></td>
<td>• <code>error</code>: Describes how the submitted object failed to conform to the schema.</td>
</tr>
</tbody>
</table>

**malformed-request**

If the request's body could not be parsed as JSON, the service returns a **400: Bad Request** response using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;malformed-request&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains two keys:</td>
</tr>
<tr>
<td></td>
<td>• <code>body</code>: Holds the request body that was received.</td>
</tr>
<tr>
<td></td>
<td>• <code>error</code>: Describes how the submitted object failed to conform to the schema.</td>
</tr>
</tbody>
</table>

**uniqueness-violation**
If your attempt to create the node group violates uniqueness constraints (such as the constraint that each node group name must be unique within its environment), the service returns a **422: Unprocessable Entity** response using the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;uniqueness-violation&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Describes which fields of the node group caused the constraint to be violated, along with their values.</td>
</tr>
<tr>
<td>details</td>
<td>An object that contains two keys:</td>
</tr>
<tr>
<td></td>
<td>• conflict: An object whose keys are the fields of the node group that violated the constraint and whose values are the corresponding field values.</td>
</tr>
<tr>
<td></td>
<td>• constraintName: The name of the database constraint that was violated.</td>
</tr>
</tbody>
</table>

**missing-referents**

If classes or class parameters defined by the node group, or inherited by the node group from its parent, do not exist in the submitted node group's environment, the service returns a **422: Unprocessable Entity** response. In both cases the response object uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;missing-referents&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Describes the error and lists the missing classes or parameters.</td>
</tr>
<tr>
<td>details</td>
<td>An array of objects, where each object describes a single missing referent, and has the following keys:</td>
</tr>
<tr>
<td></td>
<td>• kind: &quot;missing-class&quot; or &quot;missing-parameter&quot;, depending on whether the entire class doesn't exist, or the class just doesn't have the parameter.</td>
</tr>
<tr>
<td></td>
<td>• missing: The name of the missing class or class parameter.</td>
</tr>
<tr>
<td></td>
<td>• environment: The environment that the class or parameter is missing from; that is, the environment of the node group where the error was encountered.</td>
</tr>
<tr>
<td></td>
<td>• group: The name of the node group where the error was encountered. Due to inheritance, this might not be the group where the parameter was defined.</td>
</tr>
<tr>
<td></td>
<td>• defined_by: The name of the node group that defines the class or parameter.</td>
</tr>
</tbody>
</table>

**missing-parent**

If the parent of the node group does not exist, the service returns a **422: Unprocessable Entity** response. The response object uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;missing-parent&quot;</td>
</tr>
<tr>
<td>msg</td>
<td>Shows the parent UUID that did not exist.</td>
</tr>
<tr>
<td>details</td>
<td>The full submitted node group.</td>
</tr>
</tbody>
</table>
inheritance-cycle

If the request causes an inheritance cycle, the service returns a 422: Unprocessable Entity response. The response object uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>&quot;inheritance-cycle&quot;</td>
</tr>
<tr>
<td>details</td>
<td>An array of node group objects that includes each node group involved in the cycle</td>
</tr>
<tr>
<td>msg</td>
<td>A shortened description of the cycle, including a list of the node group names with each followed by its parent until the first node group is repeated.</td>
</tr>
</tbody>
</table>

Node classifier errors

Familiarize yourself with error responses to make working the node classifier service API easier.

Error response description

Errors from the node classifier service are JSON responses.

Error responses contain these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>A string classifying the error. It is the same for all errors that have the same kind of thing in their details key.</td>
</tr>
<tr>
<td>msg</td>
<td>A human-readable message describing the error, suitable for presentation to the user.</td>
</tr>
<tr>
<td>details</td>
<td>Additional machine-readable information about the error condition. The format of this key's value varies between kinds of errors but is the same for any given error kind.</td>
</tr>
</tbody>
</table>

Internal server errors

Any endpoint might return a 500: Internal Server Error response in addition to its usual responses. There are two kinds of internal server error responses: application-error and database-corruption.

An application-error response is a catchall for unexpected errors. The msg of an application-error 500 contains the underlying error's message first, followed by a description of other information that can be found in details. The details contain the error's stack trace as an array of strings under the trace key, and might also contain schema, value, and error keys if the error was caused by a schema validation failure.

A database-corruption 500 response occurs when a resource that is retrieved from the database fails to conform to the schema expected of it by the application. This is probably just a bug in the software, but it could potentially indicate either genuine corruption in the database or that a third party has changed values directly in the database. The msg section contains a description of how the database corruption could have occurred. The details section contains retrieved, schema, and error keys, which have the resource as retrieved, the schema it is expected to conform to, and a description of how it fails to conform to that schema as the respective values.

Not found errors

Any endpoint where a resource identifier is supplied can produce a 404 Not Found Error response if a resource with that identifier could not be found.

All not found error responses have the same form. The kind is "not-found", the msg is "The resource could not be found.", and the details key contains the URI of the request that resulted in this response.
Node classifier API v2

These are the endpoints for the node classifier v2 API.

- **Classification endpoint** on page 408
  The classification endpoint takes a node name and a set of facts, and returns information about how that node is classified. The output can help you test your classification rules.

**Related information**

**API index** on page 33
APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

**Classification endpoint**

The classification endpoint takes a node name and a set of facts, and returns information about how that node is classified. The output can help you test your classification rules.

- **POST /v2/classified/nodes/<name>** on page 408
  Use the /v2/classified/nodes/<name> endpoint to retrieve the classification information for the node with the given name and facts as supplied in the body of the request.

**POST /v2/classified/nodes/<name>**

Use the /v2/classified/nodes/<name> endpoint to retrieve the classification information for the node with the given name and facts as supplied in the body of the request.

**Request format**

The request body can contain a JSON object describing the facts and trusted facts of the node to be classified. The object can have these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>fact</td>
<td>The regular, non-trusted facts of the node. The value of this key is a further object, whose keys are fact names, and whose values are the fact values. Fact values can be a string, number, boolean, array, or object.</td>
</tr>
<tr>
<td>trusted</td>
<td>The trusted facts of the node. The values of this key are subject to the same restrictions as those on the value of the fact key.</td>
</tr>
</tbody>
</table>

**Response format**

The response is a JSON object describing the node post-classification, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the node (a string).</td>
</tr>
<tr>
<td>groups</td>
<td>An array of the groups that this node was classified into. The value of this key is an array of hashes containing the id and the name, sorted by name</td>
</tr>
<tr>
<td>environment</td>
<td>The name of the environment that this node uses, which is taken from the node groups the node was classified into.</td>
</tr>
<tr>
<td>classes</td>
<td>An array of the classes (strings) that this node received from the groups it was classified into.</td>
</tr>
</tbody>
</table>
### Key Definition

**parameters**

An object describing class parameter values for the above classes wherever they differ from the default. The keys of this object are class names, and the values are further objects describing the parameters for just the associated class. The keys of that innermost object are parameter names, and the values are the parameter values, which can be any sort of JSON value.

This is an example of a response from this endpoint:

```json
{
    "name": "foo.example.com",
    "groups": [{"id": "9c0c7d07-a199-48b7-9999-3cdf7654e0bf",
                  "name": "a group"},
               {"id": "96d1a058-225d-48e2-a1a8-80819d31751d",
                  "name": "b group"}],
    "environment": "staging",
    "classes": ["apache"],
    "parameters": {
        "apache": {
            "keepalive_timeout": 30,
            "log_level": "notice"
        }
    }
}
```

### Error responses

If the node is classified into multiple node groups that define conflicting classifications for the node, the service returns a 500 Server Error response.

The body of this response contains the usual JSON error object described in the errors documentation.

The **kind** key of the error is "classification-conflict", the **msg** describes generally why this happens, and the **details** key contains an object that describes the specific conflicts encountered.

The keys of these objects are the names of parameters that had conflicting values defined, and the values are arrays of value detail objects. The details object may have between one and all of the following three keys.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>Maps directly to an array of value detail objects (described below).</td>
</tr>
<tr>
<td>variables</td>
<td>Contains an object with a key for each conflicting variable, whose values are an array of value detail objects.</td>
</tr>
<tr>
<td>classes</td>
<td>Contains an object with a key for each class that had conflicting parameter definitions, whose values are further objects that describe the conflicts for that class’s parameters.</td>
</tr>
</tbody>
</table>

A value details object describes one of the conflicting values defined for the environment, a variable, or a class parameter. Each object contains these keys:
<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The defined value, which is a string for environment and class parameters, but for a variable can be any JSON value.</td>
</tr>
<tr>
<td>from</td>
<td>The node group that the node was classified into that caused this value to be added to the node's classification. This group cannot define the value, because it can be inherited from an ancestor of this group.</td>
</tr>
<tr>
<td>defined_by</td>
<td>The node group that actually defined this value. This is often the from group, but could instead be an ancestor of that group.</td>
</tr>
</tbody>
</table>

This example shows a classification conflict error object with node groups truncated for clarity:

```json
{
   "kind": "classification-conflict",
   "msg": "The node was classified into multiple unrelated groups that defined conflicting class parameters or top-level variables. See `details` for a list of the specific conflicts."
}
```

In this example, the conflicting "Blue Suede Shoes" value was included in the classification because the node matched the "Elvis Presley" group (since that is the value of the "from" key), but that group doesn't define the "Blue
Suede Shoes" value. That value is defined by the "Carl Perkins" group, which is an ancestor of the "Elvis Presley" group, causing the latter to inherit the value from the former. The other conflicting value, "Since You've Been Gone", is defined by the same group that the node matched.

**Node inventory API**

These are the endpoints for the node inventory v1 API.

**Related information**

API index on page 33

APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

**Node inventory API: forming requests**

Make well-formed HTTP(S) requests to the Puppet inventory service API.

By default, the node inventory service listens on port 8143, and all endpoints are relative to the /inventory/v1 path. For example, the full URL for the /command/create-connection endpoint on localhost is https://localhost:8143/inventory/v1/command/create-connection.

**Token authentication**

All requests made to the inventory service API require authentication. You do this for each endpoint in the service using user authentication tokens contained within the X-Authentication request header.

**Example token usage: create a connection entry**

To post a new connection entry to the inventory service when running on localhost, first generate a token with the puppet-access tool.

**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8143/inventory/v1/command/create-connection"
data='{
  "certnames": ["new.node"],
  "type": "ssh",
  "parameters": {
    "tmpdir": "/tmp",
    "port": 1234
  },
  "sensitive_parameters": {
    "username": "root",
    "password": "password"
  },
  "duplicates": "replace"
}"
curl --insecure --header "$type_header" --header "$auth_header" --request POST "$uri" --data "$data"
```

**Example token usage: query connections for a certname**

To query the /query/connections endpoint, use the same token and header pattern.

**Bash**

```bash
type_header='Content-Type: application/json'
```
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8143/inventory/v1/query/connections?certname='new.node'"

```
curl --insecure --header "$type_header" --header "$auth_header" --request POST "$uri"
```

**Related information**

**Token-based authentication** on page 208

Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

**POST /command/create-connection**

Create a new connection entry in the inventory service database.

Connection entries contain connection options, such as credentials, which are used to connect to the certnames provided in the payload via the provided connection type.

This endpoint also inserts each of the provided certnames into PuppetDB with an empty fact set, if they are not already present. After certnames have been added to PuppetDB, you can view them from the **Nodes** page in the Puppet Enterprise console. You can also add them to an inventory node list when you set up a job to run tasks.

**Important**: When the Puppet orchestrator targets a certname to run a task, it first considers the value of the **hostname** key present in the **parameters**, if available. Otherwise, it uses the value of the **certnames** key as the hostname. A good practice is to include a **hostname** key only when the hostname differs from the **certname**. Do not include a hostname key for multiple certname connection entries.

**Request format**

The request body must be a JSON object.

- **certnames**  
  **required** Array containing the list of certnames to associate with connection information.

- **type**  
  **required** String containing either ssh or winrm. Instructs bolt-server which connection type to use to access the node when running a task.

- **parameters**  
  **required** Object containing arbitrary key/value pairs. The necessary parameters for connecting to the provided certnames.

  **CAUTION**: A **hostname** key entered here takes precedence over the values in **certnames** key.

- **sensitive_parameters**  
  **required** Object containing arbitrary key/value pairs. The necessary sensitive data for connecting to the provided certnames, stored in an encrypted format.

- **duplicates**  
  **required** String containing either error or replace. Instructs how to handle cases where one or more provided certnames conflict with existing certnames stored in the inventory connections database. error results in a 409 response if any certnames are duplicates. replace overwrites the existing certnames if there are conflicts.

**Request examples**

```
{
  "certnames": ["sshnode1.example.com", "sshnode2.example.com"],
```
"type": "ssh",
"parameters": {
  "port": 1234,
  "connect-timeout": 90,
  "user": "inknowahorse",
  "run-as": "fred"
},
"sensitive_parameters": {
  "password": "password",
  "sudo-password": "xtheowl"
},
"duplicates": "replace"
}

Bash

```bash

```type_header='Content-Type: application/json'
auth_header="X-Authentication: "$(puppet-access show)"
uri="https://$(puppet config print server):8143/inventory/v1/command/create-connection"
data='{"certnames": [
  "sshnode1.example.com",
  "sshnode2.example.com"
],
  "type": "ssh",
  "parameters": {
    "port": 1234,
    "connect-timeout": 90,
    "user": "inknowahorse",
    "run-as": "fred"
  },
  "sensitive_parameters": {
    "password": "password",
    "sudo-password": "xtheowl"
  },
  "duplicates": "replace"
}

curl --insecure --header "$type_header" --header "$auth_header" --request POST "$uri" --data "$data"
```

Response format

If the request is valid according to the schema and the entry is successfully recorded in the database, the server returns a 201 response. The response has the same format for single and multiple certname entries.

The response is a JSON object containing the `connection_id`.

**connection_id**

A unique identifier that can be used to reference the record.

Response example

```
{
  "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec"
}
```

SSH parameters

To create a connection with type `ssh`, the following parameters and sensitive parameters are valid.
**parameters**

*Required.* Object containing the following key/value pairs and the necessary parameters for connecting to the provided certnames.

**user**

*Required* string. The user to log in as when connecting to the host.

**port**

*Optional* integer. Connection port with the default of 22.

**connect-timeout**

*Optional* integer. The length of time, in seconds, PE should wait when establishing connections.

**run-as**

*Optional* string. After login, the user name to use for running commands. The default is the same value as `user`.

**tmpdir**

*Optional* string. The directory to upload and execute temporary files on the target, if different than `/temp`.

**tty**

*Optional* boolean. Enable text terminal allocation.

**hostname**

*Optional* string. The hostname to connect to. Should only be provided if the desired `certname` for the newly created node within PE is different than the `hostname` of the intended target, in which case the `certname` field in the request body should be the desired `certname`, and the `hostname` field in the parameters object should be the `hostname` to connect to. As a good practice, do not provide a `hostname` key for connection entries with multiple `certnames`, and only include it if the `certname` is different from the `hostname` of the intended target. If left unspecified, the Orchestrator will connect to each host using its `certname` as the `hostname`.

**sensitive_parameters**

*Required.* Object containing arbitrary key/value pairs and the necessary sensitive data for connecting to the provided certnames, to be stored in encrypted format.

**password**

*Optional* string. Password to authenticate. One of either `password` or `private-key-content` is required.

**private-key-content**

*Optional* string. Contents of a private key. One of either `password` or `private-key-content` is required.

**sudo-password**

*Optional* string. Password to use when changing users via `run-as`. Should only be included if `run-as` is specified in the parameters object.

**WinRM parameters**

For creating a connection with type `winrm`, the following parameters and sensitive parameters are valid.

**parameters**

*Required.* Object containing the following key/value pairs and the necessary parameters for connecting to the provided certnames.

**user**

*Required* string. The user to log in as when connecting to the host.
port

*Optional* integer. Connection port with the default of 22.

connect-timeout

*Optional* integer. The length of time, in seconds, PE should wait when establishing connections.

tmpdir

*Optional* string. The directory to upload and execute temporary files on the target, if different than /temp.

extensions

*Optional* array. List of file extensions that are accepted for tasks.

hostname

*Optional* string. The hostname to connect to. Should only be provided if the desired certname for the newly created node within PE is different than the hostname of the intended target, in which case the certname field in the request body should be the desired certname, and the hostname field in the parameters object should be the hostname to connect to. As a good practice, do not provide a hostname key for connection entries with multiple certnames, and only include it if the certname is different from the hostname of the intended target. If left unspecified, the Orchestrator will connect to each host using its certname as the hostname.

sensitive_parameters

*Required*. Object containing arbitrary key/value pairs and the necessary sensitive data for connecting to the provided certnames, to be stored in an encrypted format.

password

*Required* string. The password used to authenticate.

**POST /command/delete-connection**

Delete certnames from all associated connection entries in the inventory service database and update those certname entries in the PuppetDB with the flag `preserve: false`.

**Request format**

The request body must be a JSON object containing a `certnames` key.

`certnames`

*required* Array containing the list of certnames to be removed.

**Request examples**

```json
{
    "certnames": ["avery.gooddevice", "amediocre.device"]
}
```

**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8143/inventory/v1/command/delete-connection"
data='{"certnames": ["avery.gooddevice","amediocre.device"]}''
curl --insecure --header "$type_header" --header "$auth_header"--request POST "$uri"--data "$data"
```

© 2020 Puppet, Inc.
Response format

If the request matches the schema and is processed successfully, the service responds with a 204 status code and no body payload. If the user is unauthorized, the service responds with a 403 error code.

Command endpoint error responses

General format of error responses.

Every error response from the inventory service is a JSON response. Each response is an object that contains the following keys:

kind
The kind of error encountered.

msg
The message associated with the error.

details
A hash with more information about the error.

For example, if the request is missing the required content type headers, the following error occurs:

```json
{
  "kind" : "puppetlabs.inventory/not-acceptable",
  "msg" : "accept must include content-type json",
  "details" : ""
}
```

kind error responses

For this endpoint, the kind key of the error displays the conflict.

puppetlabs.inventory/unknown-error
If an unknown error occurs during the request, the server returns a 500 response.

puppetlabs.inventory/not-acceptable
If the content provided to the API contains an "accepts" header which does not allow for JSON, the server returns a 406 response.

puppetlabs.inventory/unsupported-type
If the content provided to the API contains a "content-type" header other than JSON, the server returns a 416 response.

puppetlabs.inventory/json-parse-error
If there is an error while processing the request body, the server returns a 400 response.

puppetlabs.inventory/schema-validation-error
If there is a violation of the required format for the request body, the server returns a 400 response.

puppetlabs.inventory/not-permitted
If the user requesting an action does not have the necessary permissions to do so, the server returns a 403 response.

puppetlabs.inventory/duplicate-certnames
If the duplicates parameter is not set, or is set as error, and one or more of the certnames in the request body already exist within the inventory, the server returns a 409 response.
GET /query/connections

List all the connections entries in the inventory database.

**Request format**

The request body must be a JSON object.

- **certname**
  - *optional* String that represents the single certname to retrieve.

- **sensitive**
  - *optional* String or boolean that instructs whether to return sensitive parameters for each connection in the response. This parameter is gated by permission validation.

- **extract**
  - *optional* Array of keys to return for each certname. connection_id is always returned, regardless of whether it is included. When extract is not present in the body, all keys are returned.

  **Tip:** In order to return sensitive parameters in the extract list, the sensitive query parameter must be present and resolve to true. Otherwise, they are excluded.

**Response format**

The response is a JSON object containing the known connections. The following keys are used:

- **items**
  - Contains an array of all the known connections matching the specified (or not specified) filtering criteria. Each item under items is an object with the following keys:
    - **connection_id**
      - String that is the unique identifier for the connections entry.
    - **certnames**
      - Array of strings that contains the certnames of the matching connections entries.
    - **type**
      - String that describes the type of connection for the given information. For example, ssh or winrm.
    - **parameters**
      - Object containing arbitrary key/value pairs and describes connection options for the entry.
    - **sensitive_parameters**
      - *when specified and permitted* An object that contains arbitrary key/value pairs and describes the sensitive connection options for the entry.

**Response examples**

A response for a request to list all the connections entries in the inventory database: GET /query/connections

```json
{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["devices.arecool", "dont.youthink"],
      "type": "ssh",
      "parameters": {
        "tmpdir": "/tmp",
        "port": 1234
      }
    }
  ]
}
```

© 2020 Puppet, Inc.
A response for a request to list a specific certname: GET /query/connections?certname="averygood.device"

{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["averygood.device"],
      "type": "ssh",
      "parameters": {
        "tmpdir": "/tmp",
        "port": 1234
      }
    }
  ]
}

A response for request to list a specific certname and its sensitive parameters: GET /query/connections?certname="averygood.device"&sensitive=true example

{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["averygood.device"],
      "type": "ssh",
      "parameters": {
        "tmpdir": "/tmp",
        "port": 1234
      },
      "sensitive_parameters": {
        "username": "johnjohnjimmyjohn",
        "password": "C7b0$1s8lt0"
      }
    }
  ]
}

A response for request to list a specific certname and its value for the type key: GET /query/connections?certname="averygood.device"&extract=["type"]

{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["averygood.device"],
      "type": "ssh"
    }
  ]
}
**POST /query/connections**
Retrieve inventory connections in bulk via certname.

**Request format**
The request body must be a JSON object.

- `certnames`  
  Array containing the list of certnames to retrieve from the inventory database. If this key is not included, all connections are returned.

- `extract`  
  Array of keys to return for each certname. `connection_id` is always returned, regardless of whether it is included. When `extract` is not present in the body, all keys are returned.

  **Tip:** In order to return sensitive parameters in the `extract` list, the `sensitive` query parameter must be present and resolve to true. Otherwise, they are excluded.

- `sensitive`  
  Optional String or boolean that instructs whether to return sensitive parameters for each connection in the response. This parameter is gated by permission validation.

**Response format**
The response is a JSON object containing the known connections. The following keys are used:

- `items`  
  Contains an array of all the known connections matching the specified (or not specified) filtering criteria. Each item under `items` is an object with the following keys:

  - `connection_id`  
    String that is the unique identifier for the connections entry.

  - `certnames`  
    Array of strings that contains the certnames of the matching connections entries.

  - `type`  
    String that describes the type of connection for the given information. For example, `ssh` or `winrm`.

  - `parameters`  
    Object containing arbitrary key/value pairs and describes connection options for the entry.

  - `sensitive_parameters`  
    An object that contains arbitrary key/value pairs and describes the sensitive connection options for the entry.

**Request and response examples**
An empty request body.

```json
{}
```

A response for an empty request.

```json
{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["devices.arecool", "dont.youthink"],
      "type": "winrm",
      "parameters": {
```
"tmpdir": "/tmp",
"port": 1234
},
},
"connection_id": "4932bfe7-69c4-412f-b15c-ac0a7c2883f1",
"certnames": ["managing.devices", "is.evencooler"],
"type": "ssh",
"parameters": {
  "tmpdir": "/tmp",
  "port": 1234
}
]
]
}
}

A certnames request body.

{
  "certnames": ["averygood.device"]
}

A response for a certnames request.

{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["averygood.device"],
      "type": "ssh",
      "parameters": {
        "tmpdir": "/tmp",
        "port": 1234
      }
    }
  ]
}

A request to list a specific certname and its sensitive parameters: /query/connections?Sensitive=true

{
  "certnames": ["averygood.device"],
  "extract": ["certnames", "sensitive_parameters"]
}

A response for a request for a specific certname and its sensitive parameters.

{
  "items": [
    {
      "connection_id": "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
      "certnames": ["averygood.device"],
      "sensitive_parameters": {
        "username": "johnjohnjimmyjohn",
        "password": "C7b0$1s81tO"
      }
    }
  ]
}

© 2020 Puppet, Inc.
Query endpoint error responses

General format of error responses.

Every error response from the inventory service is a JSON response. Each response is an object that contains the following keys:

kind
  The kind of error encountered.

msg
  The message associated with the error.

details
  A hash with more information about the error.

For example, if the request is missing the required content type headers, the following error occurs:

```json
{
  "kind" : "puppetlabs.inventory/not-acceptable",
  "msg" : "accept must include content-type json",
  "details" : ""
}
```

kind error responses

For this endpoint, the kind key of the error displays the conflict.

puppetlabs.inventory/unknown-error
  If an unknown error occurs during the request, the server returns a 500 response.

puppetlabs.inventory/not-acceptable
  If the content provided to the API contains an "accepts" header which does not allow for JSON, the server returns a 406 response.

puppetlabs.inventory/unsupported-type
  If the content provided to the API contains a "content-type" header other than JSON, the server returns a 416 response.

puppetlabs.inventory/json-parse-error
  If there is an error while processing the request body, the server returns a 400 response.

puppetlabs.inventory/schema-validation-error
  If there is a violation of the required format for the request body, the server returns a 400 response.

Managing patches

Use Puppet Enterprise to configure patching node groups to meet your needs, view available operating system patches for your nodes in the console, and apply patches using the pe_patch::patch_server task.
• Configuring patch management on page 422
To enable patch management, create a node group for nodes you want to patch and add the node group to the **PE Patch Management** parent node group.

• Patching nodes on page 427
You can start viewing available patches and applying them to your nodes using the `pe_patch::patch_server` task after you have set up patch management.

### Configuring patch management
To enable patch management, create a node group for nodes you want to patch and add the node group to the **PE Patch Management** parent node group.

### Patch management OS compatibility
Patch management is compatible with select agent operating systems.

**Note:** If your operating system does not support TLSv1.2, see Enable TLSv1 on page 646 to enable older protocols.

### Where patch information comes from
Your package management software is responsible for ensuring PE can find the latest patch information available.

The `pe_patch` module uses OS level tools or APIs to patch nodes. You still have to manage the configuration of your package manager, like YUM, APT, Zyper, or Windows Update, so your nodes can search for updates. For example, if you need to go through a proxy and you use YUM, you must configure this on your own.

### Configure Windows Update
If you are using Windows Update, we recommend you use the `puppetlabs/wsus_client` module and configure these parameters in the `wsus_client` class.

• Set the `server_url` parameter to the URL of your WSUS server.
• Change the `auto_update_options` parameter to `AutoNotify` to automatically download updates and notify users.

**Create a node group for nodes under patch management**

Create a node group for nodes you want to patch in PE and add nodes to it. For example, create a node group for testing Windows and *nix patches prior to rolling out patches to other node groups. The PE Patch Management parent node group has the `pe_patch` class assigned to it and is in the console by default.

**Note:** Adding PE infrastructure nodes to patch management node groups can cause service interruptions when certain patches are applied.

1. In the console, click **Node groups**, and click **Add group**.
2. Specify options for the new node group, then click **Add**.
   - Parent name – Select **PE Patch Management**.
   - Group name – Enter a name that describes the role of the node group, for example, **patch test**.
   - Environment – Select **production**.
   - Environment group – Do not select this option.
3. Select the patching node group you created.
4. On the **Node group details** page, on the **Rules** tab, add nodes to the group by either pinning them individually or adding a rule to automatically add nodes that meet your specifications.

  **CAUTION:** Do not include the same node in multiple node groups under patch management. This might cause classification conflicts.
5. Select **Run > Puppet** in the top right corner of the page.

PE can now manage patches for the nodes in your new node group. Repeat these steps to add any additional node groups you want under patch management.

**Related information**

*Add nodes to a node group* on page 297

There are two ways to add nodes to a node group.

**Specify patching parameters**

Set parameters for node groups under patch management by first applying the `pe_patch` class to them, then specifying your desired parameters in the console.

**Before you begin**

Create at least one node group under patch management.

1. On the **Node groups** page, select the patching node group you want to add parameters to.
2. On the **Classes** tab, enter `pe_patch` and select **Add class**. You must add the `pe_patch` class before you can specify parameters.
3. Commit changes.
4. On the **Classes** tab, under **Parameter**, add the desired parameters to the `pe_patch` class.

   For example, you can add the `patch_group` parameter, which lets you add a tag of your choice, expressed as a string, to your node group. Use this to do things like limit permissions for a user to only run the `pe_patch` task on node groups that have a specific tag. If applied, you can view the tag under the **Patch group** field in the table in the **Apply patches** section of the **Patches** page.
5. Commit changes.
Assign a patch management blackout window
Apply a blackout window to prevent PE from applying patches to nodes for a specified duration of time. For example, limit applying patches during an end-of-year change freeze.

Before you begin
Assign the pe_patch class to the applicable node group. See Specify patching parameters on page 423 for more information.

1. On the Node groups page, select the patching node group you want to assign a blackout window to.
2. On the Classes tab, under Parameter, add the blackout_windows parameter to the pe_patch class.
3. In the Value field, enter your blackout window as a JSON hash of keys and an ISO compliant timestamp.
   For example, an end of year blackout window from the beginning of the day on 15 December 2020 to the end of the day on 15 January 2021 looks like this:

   ```json
   {
       "End of year change freeze": {
           "start": "2020-12-15T00:00:00+10:00",
           "end": "2021-01-15T23:59:59+10:00"
       }
   }
   ```

4. Commit changes.

Patch management parameters
Configure and tune patch management by adjusting parameters in the pe_patch class.

**patch_data_owner**
User name for the owner of the patch data. String.
Default: root

**patch_data_group**
Group name for the owner of the patch data. String.
Default: root

**patch_cron_user**
User who runs the cron job. String.
Default: $patch_data_owner

**manage_yum-utils**
Determines if the yum_utils package should be managed by this module on RedHat family nodes. If true, use the yum_utils parameter to determine how it should be managed. Boolean.
Default: false

**yum-utils**
If managed, determines what the package is set to. Enum[installed, absent, purged, held, latest]
Default: installed

**block_patching_on_warnings**
Determines if the patching task should run if there were warnings present on the pe_patch fact. If true, the run will abort and take no action. If false, the run will continue and attempt to patch. Boolean.
Default: false

**fact_upload**
Determines if puppet fact upload runs after any changes are made to the fact cache files. Boolean.
Default: true
apt_autoremove
Determines if `apt-get autoremove` runs during reboot. Boolean.
Default: false

manage_delta_rpm
Determines if the `delta_rpm` package should be managed by this module on RedHat family nodes. If `true`, use the `delta_rpm` parameter to determine how it should be managed. Boolean.
Default: false

delta_rpm
If managed, determines what the `delta_rpm` package is set to. Enum[installed, absent, purged, held, latest]
Default: installed

manage_yum_plugin_security
Determines if the `yum_plugin_security` package should be managed by this module on RedHat family nodes. If `true`, use the `yum_plugin_security` parameter to determine how it should be managed. Boolean.
Default: false

yum_plugin_security
If managed, determines what the `yum_plugin_security` package is set to. Enum[installed, absent, purged, held, latest]
Default: installed

reboot_override
Determines if a node reboots after patching. This overrides the setting in the task. Variant, Boolean, Enum[always, never, patched, smart, default]
• always - The node always reboots during the task run, even if no patches are required.
• never (or false) - The node never reboots during the task run, even if patches are applied.
• patched (or true) - The node reboots if patches are applied.
• smart - Use the OS supplied tools, like `needs_restarting` on RHEL or a pending reboot check on Windows, to determine if a reboot is required, if it is reboots, or if it does not reboot.
• default - Uses whatever option is set in the `reboot` parameter for the `pe_patch::patch_server` task.
Default: default

patch_group
Allocates a node to a specific patch group. Optional string.
Default: undef

pre_patching_command
The full path of the command to run prior to running patching. Can be used to run customised workflows such as shutting down applications. The entry must be a single absolute filename with no arguments or parameters.
Default: undef

patch_cron_hour
The hour or hours for the cron job to run.
Default: absent, or *

patch_cron_month
The month or months for the cron job to run.
Default: absent, or *
patch_cron_monthday
The monthday or monthdays for the cron job to run.
Default: absent, or *

patch_cron_weekday
The weekday or weekdays for the cron job to run.
Default: absent, or *

patch_cron_min
The min or mins for the cron job to run.
Default: fqdn_rand(59) - a random number between 0 and 59.

ensure
Use present to install scripts, cronjobs, files, etc. Use absent to clean up system that previously hosted.
Default: present

blackout_windows
Determines a window of time when nodes cannot be patched. Hash.
:title - Name of the blackout window. String.
:start - Start of the blackout window (ISO8601 format). String.
:end - End of the blackout window (ISO8601 format). String.
Default: undef

Patching task parameters
The pe_patch::patch_server task applies patches to nodes. When you patch nodes in the console, most of the information for the patch_server task is prefilled on the Run a task page, but you can add additional parameters to the task before you run it. Here are the optional parameters that are available.

reboot
Determines if the server should reboot after applying patches. [Boolean, Enum [always, never, patched, smart]]
- always - The node always reboots during the task run, even if no patches are required.
- never (or false) - The node never reboots during the task run, even if patches are applied.
- patched (or true) - The node reboots if patches are applied.
- smart - Use the OS supplied tools, like needs_restarting on RHEL or a pending reboot check on Windows, to determine if a reboot is required, if it is reboots, or if it does not reboot.
Default: never

timeout
Determines how many seconds before the task run times out. Integer.
Default: 3600 (seconds)

yum_params
Indicates what additional parameters to include in the yum upgrade command, such as including or excluding repos. String.
Default: undef

clean_cache
Indicates if the yum/dpkg caches are cleaned at the start of the task. Boolean.
Default: false
dpkg_params
Indicates what additional parameters to include in the dpkg command. String.
Default: undef

security_only
Determines whether to include only security patches in a task run. Boolean.
Default: false

zypper_params
Indicates what additional parameters to include in the zypper update command. String.
Default: undef

**Patching nodes**

You can start viewing available patches and applying them to your nodes using the `pe_patch::patch_server` task after you have set up patch management.

**Patch nodes**

Select patches and then apply them by running the `pe_patch::patch_server` task. Limit patches to security or non-security updates, Windows or *nix nodes, or a specific patch group.

**Before you begin**

Ensure you have permission to run the `pe_patch::patch_server` task. The `pe_patch::patch_server` task is what applies patches and optionally reboots the selected nodes.

1. On the **Patches** page, in the **Apply patches** section, use the filters to specify which patches to apply to which nodes.

   **Note:** Filters use **and** logic. This means that if you select **Security updates** and **Windows**, the results include security patches for Windows nodes, not all security patches and all Windows patches.

2. Select **Run > Task**.

   The **Run a task** page appears with patching information pre-filled for the `pe_patch::patch_server` task.

3. Optional: In the **Job details** field, provide a description of the task run. This appears on the **Tasks** page.

4. Optional: Under **Task parameters**, add optional parameters to the task. See **Patching task parameters** on page 426 for a full list of available parameters.

   **Note:** You must click **Add parameter** for each optional parameter-value pair you add to the task.

5. Optional: If you want to schedule the task to run later, under **Schedule**, select **Later** and choose a time.

6. Select **Run task** to apply patches.

To check the status of the task, look for it on the **Tasks** page. You can filter the results to view only `pe_patch` tasks.

**Note:** When using patch management to update core packages that affect the networking stack, the task run might look like it failed due to the PXP agent on the node losing connection with the master. However, the task still completes successfully. You can confirm by checking the `pe_patch` fact to verify the relevant packages were updated.
Orchestrating Puppet, tasks, and plans

Puppet orchestrator is an effective tool for making on-demand changes to your infrastructure.

With orchestrator you can:

- Automate tasks and plans tasks to eliminate manual work across your infrastructure and applications.
- Initiate Puppet jobs whenever you need to update agents.
- Group the servers in your network according to immediate business needs. By leveraging orchestrator with PuppetDB, which stores detailed information about your nodes, you can search and filter servers based on metadata. No static lists of hosts, no reliance on complicated host-naming conventions.
- Connect with thousands of hosts at the same time without slowing down your network. The Puppet Communications Protocol (PCP) and message broker efficiently mediate communications on your network even as your operational demands grow.
- Distribute the Puppet agent workload by adding masters that are dedicated to catalog compilation as you increase in scale. Compilers efficiently process requests and compile code for environments that have thousands of nodes. For more information, see Installing compilers on page 125.
- Take advantage of the tasks installed with PE. Use the package task to inspect, install, upgrade, and manage packages or the service task to start, stop, restart, and check the status of services running on your systems. Additional tasks are available from the Puppet Forge.
- Write your own tasks in any programming language that your target nodes can run, such as Bash, PowerShell, or Python.
- Write plans in Puppet or YAML or download them from the Forge.
- Integrate server logging, auditing, and per node role-based access control (RBAC).
- Use plans to create customized permissions for tasks.

Running jobs with Puppet orchestrator on page 429

With the Puppet orchestrator, you can run three types of "jobs": on-demand Puppet jobs, task runs, and plan runs.

Configuring Puppet orchestrator on page 431

Once you've installed PE or the client tools package, there are a few tasks you need to do to prepare your PE infrastructure for orchestration services.

Direct Puppet: a workflow for controlling change on page 438

The orchestrator—used alongside other PE tools, such as Code Manager—allows you to control when and how infrastructure changes are made before they reach your production environment.

Running Puppet on demand on page 441

The orchestrator gives you the ability to set up jobs in the console or on the command line to trigger on-demand Puppet runs.

Tasks and plans in PE on page 458

Use the orchestrator to run tasks and plans in the console or on the command line.

Writing tasks on page 477

Bolt tasks are similar to scripts, but they are kept in modules and can have metadata. This allows you to reuse and share them.

Writing plans on page 494

Plans allow you to run more than one task with a single command, compute values for the input to a task, process the results of tasks, or make decisions based on the result of running a task.

Puppet orchestrator API v1 endpoints on page 526

Use this API to gather details about the orchestrator jobs you run.

Migrating Bolt tasks and plans to PE on page 574

If you use Bolt tasks and plans to automate parts of your configuration management, you can move that Bolt content to a control repo and transform it into a PE environment. This lets you manage and run tasks and plans using PE and the console. PE environments and Bolt projects use the same default structure, and both use a Puppetfile to install content.
Running jobs with Puppet orchestrator

With the Puppet orchestrator, you can run three types of "jobs": on-demand Puppet jobs, task runs, and plan runs.

When you run Puppet on-demand with the orchestrator, you control the rollout of configuration changes when and how you want them. You control when Puppet jobs run and where node catalogs are applied (from the environment level to an individual node). You no longer need to wait on arbitrary run times to update your nodes.

Puppet tasks allow you to execute actions on target machines. A "task" is a single action that you execute on the target via an executable file. For example, do you want to upgrade a package or restart a particular service? Set up a Puppet task run to enforce to make those changes at will.

Puppet plans are bundles of tasks that can be combined with other logic. They allow you to do complex task operations, like running multiple tasks with one command or automatically running certain tasks based on the output of another task.

Tasks and plans are packaged and distributed as Puppet modules.

Puppet orchestrator technical overview

The orchestrator uses pe-orchestration-services, a JVM-based service in PE, to execute on-demand Puppet runs on agent nodes in your infrastructure. The orchestrator uses PXP agents to orchestrate changes across your infrastructure.

The orchestrator (as part of pe-orchestration-services) controls the functionality for the puppet-job and puppet-app commands, and also controls the functionality for jobs and single node runs in the PE console.

The orchestrator is comprised of several components, each with their own configuration and log locations.

Puppet orchestrator architecture

The functionality of the orchestrator is derived from the Puppet Execution Protocol (PXP) and the Puppet Communications Protocol (PCP).

- PXP: A message format used to request that a task be executed on a remote host and receive responses on the status of that task. This is used by the pe-orchestration services to run Puppet on agents.
- PXP agent: A system service in the agent package that runs PXP.
- PCP: The underlying communication protocol that describes how PXP messages get routed to an agent and back to the orchestrator.
- PCP broker: A JVM-based service that runs in pe-orchestration-services on the master and in the pe-puppetserver service on compilers. PCP brokers route PCP messages, which declare the content of the message via message type, and identify the sender and intended recipient. PCP brokers on compilers connect to the orchestrator, and the orchestrator uses the brokers to direct messages to PXP agents connected to the compilers. When using compilers, PXP agents running on PE components (the Puppet master, PuppetDB, and the PE console) connect directly to the orchestrator, but all other PXP agents connect to compilers via load balancers.

What happens during an on-demand run from the orchestrator?

Several PE services interact when you run Puppet on demand from the orchestrator.

1. You use the puppet-job command to create a job in orchestrator.
2. The orchestrator validates your token with the PE RBAC service.
3. The orchestrator requests environment classification from the node classifier for the nodes targeted in the job, and it queries PuppetDB for the nodes.
4. The orchestrator requests the environment graph from Puppet Server.
5. The orchestrator creates the job ID and starts polling nodes in the job to check their statuses.
6. The orchestrator queries PuppetDB for the agent version on the nodes targeted in the job.
7. The orchestrator tells the PCP broker to start runs on the nodes targeted in the job, and Puppet runs start on those agents.
8. The agent sends its run results to the PCP broker.
9. The orchestrator receives run results, and requests the node run reports from PuppetDB.

What happens during a task run from the orchestrator?

Several services interact for a task run as well. Because tasks are Puppet code, they must be deployed into an environment on the Puppet master. Puppet Server then exposes the task metadata to the orchestrator. When a task is run, the orchestrator sends the PXP agent a URL of where to fetch the task from the master and the checksum of the task file. The PXP agent downloads the task file from the URL and caches it for future use. The file is validated against the checksum before every execution. The following are the steps in this process.

1. The PE client sends a task command.
2. The orchestrator checks if a user is authorized.
3. The orchestrator fetches the node target from PuppetDB if the target is a query, and returns the nodes.
4. The orchestrator requests task data from Puppet Server.
5. Puppet Server returns task metadata, file URIs, and file SHAs.
6. The orchestrator validates the task command and then sends the job ID back to the client.
7. The orchestrator sends task parameters and file information to the PXP agent.
8. The PXP agent sends a provisional response to the orchestrator, checks the SHA against the local cache, and requests the task file from Puppet Server.
9. Puppet Server returns the task file to the PXP agent.
10. The task runs.
11. The PXP agent sends the result to the orchestrator.
12. The client requests events from the orchestrator.
13. The orchestrator returns the result to the client.

Configuration notes for the orchestrator and related components

Configuration and tuning for the components in the orchestrator happens in various files.

- **pe-orchestration-services**: The underlying service for the orchestrator. The main configuration file is `/etc/puppetlabs/orchestration-services/conf.d`
  
  Additional configuration for large infrastructures can include tuning the pe-orchestration-services JVM heap size, increasing the limit on open file descriptors for pe-orchestration-services, and tuning ARP tables.

- **PCP broker**: Part of the pe-puppetserver service. The main configuration file is `/etc/puppetlabs/puppetserver/conf.d`
  
  The PCP broker requires JVM memory and file descriptors, and these resources scale linearly with the number of active connections. Specifically, the PCP broker requires:
  
  - Approximately 40 KB of memory (when restricted with the `-Xmx` JVM option)
  - One file descriptor per connection
  - An approximate baseline of 60 MB of memory and 200 file descriptors
  
  For a deployment of 100 agents, expect to configure the JVM with at least `-Xmx64m` and 300 file descriptors. Message handling requires minimal additional memory.

- **PXP agent**: Configuration is managed by the agent profile (`puppet_enterprise::profile::agent`).

  The PXP agent is configured to use Puppet’s SSL certificates and point to one PCP broker endpoint. If disaster recovery is configured, the agent points to additional PCP broker endpoints in the case of failover.

  **Note**: If you reuse an existing agent with a new orchestrator instance, you must delete the pxp-agent spool directory, located at `/opt/puppetlabs/pxp-agent/spool` (*nix) or `C:\ProgramData\PuppetLabs\pxp-agent\var\spool` (Windows)

Debugging the orchestrator and related components

If you need to debug the orchestrator or any of its related components, the following log locations might be helpful.
• pe-orchestration-services: The main log file is `/var/log/puppetlabs/orchestration-services/orchestration-services.log`.

• PCP: The main log file for PCP brokers on compilers is `/var/log/puppetlabs/puppetserver/pcp-broker.log`. You can configure logback through the Puppet server configuration.

The main log file for PCP brokers on the master is `/var/log/puppetlabs/orchestration-services/pcp-broker.log`.

You can also enable an access log for messages.

• PXP agent: The main log file is `/var/log/puppetlabs/pxp-agent/pxp-agent.log` (on *nix) or `C:/ProgramData/PuppetLabs/pxp-agent/var/log/pxp-agent.log` (on Windows). You can configure this location as necessary.

Additionally, metadata about Puppet runs triggered via the PXP agent are kept in the spool-dir, which defaults to `/opt/puppetlabs/pxp-agent/spool` (on *nix) and or `C:/ProgramData/PuppetLabs/pxp-agent/var/spool` (on Windows). Results are kept for 14 days.

## Configuring Puppet orchestrator

Once you’ve installed PE or the client tools package, there are a few tasks you need to do to prepare your PE infrastructure for orchestration services.

• Set PE RBAC permissions and token authentication for Puppet orchestrator

• Enable cached catalogs for use with the orchestrator (optional)

• Review the orchestrator configuration files and adjust them as needed

All of these instructions assume that PE client tools are installed.

### Related information

[Installing PE client tools](#) on page 129

PE client tools are a set of command line tools that let you access Puppet Enterprise services from a workstation that might or might not be managed by Puppet.

## Orchestration services settings

### global.conf: Global logging and SSL settings

`/etc/puppetlabs/orchestration-services/conf.d/global.conf` contains settings shared across the Puppet Enterprise (PE) orchestration services.

The file `global.certs` typically requires no changes and contains the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl-cert</td>
<td>Certificate file path for the orchestrator host.</td>
<td><code>/etc/puppetlabs/orchestration-services/ssl/&lt;orchestrator-host-fqdn&gt;.cert.pem</code></td>
</tr>
<tr>
<td>ssl-key</td>
<td>Private key path for the orchestrator host.</td>
<td><code>/etc/puppetlabs/orchestration-services/ssl/&lt;orchestrator-host-fqdn&gt;.private_key.pem</code></td>
</tr>
<tr>
<td>ssl-ca-cert</td>
<td>CA file path</td>
<td><code>/etc/puppetlabs/puppet/ssl/ca.pem</code></td>
</tr>
</tbody>
</table>
The file `global.logging-config` is a path to `logback.xml` file that configures logging for most of the orchestration services. See [http://logback.qos.ch/manual/configuration.html](http://logback.qos.ch/manual/configuration.html) for documentation on the structure of the `logback.xml` file. It configures the log location, rotation, and formatting for the following:

- orchestration-services (appender section `F1`)
- orchestration-services status (STATUS)
- pcp-broker (PCP)
- pcp-broker access (PCP_ACCESS)
- aggregate-node-count (AGG_NODE_COUNT)

**bootstrap.cfg: Allow list of trapperkeeper services to start**

`/etc/puppetlabs/orchestration-services/bootstrap.cfg` is the list of trapperkeeper services from the orchestrator and pcp-broker projects that are loaded when the `pe-orchestration-services` system service starts.

- To disable a service in this list, remove it or comment it with a `#` character and restart `pe-orchestration-services`
- To enable an NREPL service for debugging, add `puppetlabs.trapperkeeper.services.nrepl.nrepl-service/nrepl-service` to this list and restart `pe-orchestration-services`.

**webserver.conf and web-routes.conf: The pcp-broker and orchestrator HTTP services**

`/etc/puppetlabs/orchestration-services/conf.d/webserver.conf` describes how and where to run pcp-broker and orchestrator web services, which accept HTTP API requests from the rest of the PE installation and from external nodes and users.

The file `webserver.orchestrator` configures the orchestrator web service. Defaults are as follows:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-log-config</td>
<td>A logback XML file configuring logging for orchestrator access messages.</td>
<td><code>/etc/puppetlabs/orchestration-services/request-logging.xml</code></td>
</tr>
<tr>
<td>client-auth</td>
<td>Determines the mode that the server uses to validate the client's certificate for incoming SSL connections.</td>
<td><code>want</code> or <code>need</code></td>
</tr>
<tr>
<td>default-server</td>
<td>Allows multi-server configurations to run operations without specifying a server-id. Without a server-id, operations will run on the selected default. Optional.</td>
<td><code>true</code></td>
</tr>
<tr>
<td>ssl-ca-cert</td>
<td>Sets the path to the CA certificate PEM file used for client authentication.</td>
<td><code>/etc/puppetlabs/puppet/ssl/certs/ca.pem</code></td>
</tr>
<tr>
<td>ssl-cert</td>
<td>Sets the path to the server certificate PEM file used by the web service for HTTPS.</td>
<td><code>/etc/puppetlabs/orchestration-services/ssl/&lt;orchestrator-host-fqdn&gt;.cert.pem</code></td>
</tr>
<tr>
<td>ssl-crl-path</td>
<td>Describes a path to a Certificate Revocation List file. Optional.</td>
<td><code>/etc/puppetlabs/puppet/ssl/crl.pem</code></td>
</tr>
<tr>
<td>ssl-host</td>
<td>Sets the host name to listen on for encrypted HTTPS traffic.</td>
<td><code>0.0.0.0</code>.</td>
</tr>
</tbody>
</table>
### Setting | Definition | Default
--- | --- | ---
ssl-key | Sets the path to the private key PEM file that corresponds with the ssl-cert. | /etc/puppetlabs/orchestration-services/ssl/<orchestrator-host-fqdn>.private_key.pem
ssl-port | Sets the port to use for encrypted HTTPS traffic. | 8143

The file `webserver.pcp-broker` configures the pcp-broker web service. Defaults are as follows:

| Setting | Definition | Default
--- | --- | ---
client-auth | Determines the mode that the server uses to validate the client's certificate for incoming SSL connections. | want or need
ssl-ca-cert | Sets the path to the CA certificate PEM file used for client authentication. | /etc/puppetlabs/puppet/ssl/certs/ca.pem
ssl-cert | Sets the path to the server certificate PEM file used by the web service for HTTPS. | /etc/puppetlabs/orchestration-services/ssl/<orchestrator-host-fqdn>.cert.pem
ssl-crl-path | Describes a path to a Certificate Revocation List file. Optional. | /etc/puppetlabs/puppet/ssl/crl.pem
ssl-host | Sets the host name to listen on for encrypted HTTPS traffic. | 0.0.0.0.
ssl-key | Sets the path to the private key PEM file that corresponds with the ssl-cert. | /etc/puppetlabs/orchestration-services/ssl/<orchestrator-host-fqdn>.private_key.pem
ssl-port | Sets the port to use for encrypted HTTPS traffic. | 8142

/`etc/puppetlabs/orchestration-services/conf.d/web-routes.conf` describes how to route HTTP requests made to the API web servers, designating routes for interactions with other services. These should not be modified. See the configuration options at the trapperkeeper-webserver-jetty project's docs.

**analytics.conf**: Analytics trapperkeeper service configuration

/`etc/puppetlabs/orchestration-services/conf.d/analytics.conf` contains the internal setting for the analytics trapperkeeper service.

| Setting | Definition | Default
--- | --- | ---
analytics.url | Specifies the API root. | <puppetserver-host-url>:8140/analytics/v1

**auth.conf**: Authorization trapperkeeper service configuration

/`etc/puppetlabs/orchestration-services/conf.d/auth.conf` contains internal settings for the authorization trapperkeeper service. See configuration options in the trapperkeeper-authorization project's docs.
metrics.conf: JMX metrics trapperkeeper service configuration
/etc/puppetlabs/orchestration-services/conf.d/metrics.conf contains internal settings for the JMX metrics service built into orchestration-services. See the service configuration options in the trapperkeeper-metrics project's docs.

orchestrator.conf: Orchestrator trapperkeeper service configuration
/etc/puppetlabs/orchestration-services/conf.d/orchestrator.conf contains internal settings for the orchestrator project's trapperkeeper service.

pcp-broker.conf: PCP broker trapperkeeper service configuration
/etc/puppetlabs/orchestration-services/conf.d/pcp-broker.conf contains internal settings for the pcp-broker project's trapperkeeper service. See the service configuration options in the pcp-broker project's docs.

Setting PE RBAC permissions and token authentication for orchestrator

Before you run any orchestrator jobs, you need to set the appropriate permissions in PE role-based access control (RBAC) and establish token-based authentication.

Most orchestrator users require the following permissions to run orchestrator jobs or tasks:

<table>
<thead>
<tr>
<th>Type</th>
<th>Permission</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Puppet agent</td>
<td>Run Puppet on agent nodes.</td>
<td>The ability to run Puppet on nodes using the console or orchestrator. Instance must always be &quot;*&quot;.</td>
</tr>
<tr>
<td>Job orchestrator</td>
<td>Start, stop and view jobs</td>
<td>The ability to start and stop jobs and tasks, view jobs and job progress, and view an inventory of nodes that are connected to the PCP broker.</td>
</tr>
<tr>
<td>Tasks</td>
<td>Run tasks</td>
<td>The ability to run specific tasks on all nodes, a selected node group, or nodes that match a PQL query.</td>
</tr>
<tr>
<td>Nodes</td>
<td>View node data from PuppetDB.</td>
<td>The ability to view node data imported from PuppetDB. Object must always be &quot;*&quot;.</td>
</tr>
</tbody>
</table>

Note: If you do not have permissions to view a node group, or the node group doesn't have any matching nodes, that node group won't be listed as an option for viewing. In addition, a node group does not appear if no rules have been specified for it.

Assign task permissions to a user role

1. In the console, on the Access control page, click the User roles tab.
2. From the list of user roles, click the one you want to have task permissions.
3. On the Permissions tab, in the Type box, select Tasks.
4. For Permission, select Run tasks, and then select a task from the Object list. For example, facter_task.
5. Click Add permission, and then commit the change.

Using token authentication

Before running an orchestrator job, you must generate an RBAC access token to authenticate to the orchestration service. If you attempt to run a job without a token, PE prompts you to supply credentials.
For information about generating a token with the CLI, see the documentation on token-based authentication.

**Related information**

Token-based authentication on page 208

Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

Create a new user role on page 200

RBAC has four predefined roles: Administrators, Code Deployers, Operators, and Viewers. You can also define your own custom user roles.

Assign permissions to a user role on page 200

You can mix and match permissions to create custom user roles that provide users with precise levels of access to PE actions.

**Orchestrator configuration files**

The configuration file for the orchestrator allows you to run commands from the CLI without having to pass additional flags. Whether you are running the orchestrator from the Puppet master or from a separate workstation, there are two types of configuration files: a global configuration file and a user-specified configuration file.

**Orchestrator global configuration file**

If you're running the orchestrator from a PE-managed machine, on either the Puppet master or an agent node, PE manages the global configuration file.

This file is installed on both managed and non-managed workstations at:

* \*nix systems --- /etc/puppetlabs/client-tools/orchestrator.conf

* Windows --- C:/ProgramData/PuppetLabs/client-tools/orchestrator.conf

The class that manages the global configuration file is `puppet_enterprise::profile::controller`. The following parameters and values are available for this class:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>manage_orchestrator</td>
<td>true or false (default is true)</td>
</tr>
<tr>
<td>orchestrator_url</td>
<td>url and port (default is Puppet master url and port 8143)</td>
</tr>
</tbody>
</table>

The only value PE sets in the global configuration file is the `orchestrator_url` (which sets the orchestrator's service-url in `/etc/puppetlabs/client-tools/orchestrator.conf`).

**Important:** If you're using a managed workstation, do not edit or change the global configuration file. If you're using an unmanaged workstation, you can edit this file as needed.

**Orchestrator user-specified configuration file**

You can manually create a user-specified configuration file and populate it with orchestrator configuration file settings. PE does not manage this file.

This file needs to be located at `~/.puppetlabs/client-tools/orchestrator.conf` for both \*nix and Windows.

If present, the user specified configuration always takes precedence over the global configuration file. For example, if both files have contradictory settings for the `environment`, the user specified settings prevail.

**Orchestrator configuration file settings**

The orchestrator configuration file is formatted in JSON. For example:

```json
{
}
```
"options" : {
  "service-url": "https://<PUPPET MASTER HOSTNAME>:8143",
  "cacert": "/etc/puppetlabs/puppet/ssl/certs/ca.pem",
  "token-file": "~/.puppetlabs/token",
  "color": true
}
}

The orchestrator configuration files (the user-specified or global files) can take the following settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>service-url</td>
<td>The URL that points to the Puppet master and the port used to communicate with the orchestration service. (You can set this with the orchestrator_url parameter in the puppet_enterprise::profile::controller class.) Default value: https://&lt;PUPPET MASTER HOSTNAME&gt;:8143</td>
</tr>
<tr>
<td>environment</td>
<td>The environment used when you issue commands with Puppet orchestrator.</td>
</tr>
<tr>
<td>cacert</td>
<td>The path for the Puppet Enterprise CA cert.</td>
</tr>
<tr>
<td></td>
<td>*nix: /etc/puppetlabs/puppet/ssl/certs/ca.pem</td>
</tr>
<tr>
<td></td>
<td>Windows: C:\ProgramData\PuppetLabs\puppet\etc\ssl\certs\ca.pem</td>
</tr>
<tr>
<td>token-file</td>
<td>The location for the authentication token. Default value: ~/.puppetlabs/token</td>
</tr>
<tr>
<td>color</td>
<td>Determines whether the orchestrator output uses color. Set to true or false.</td>
</tr>
<tr>
<td>noop</td>
<td>Determines whether the orchestrator runs the Puppet agent in no-op mode. Set to true or false.</td>
</tr>
</tbody>
</table>

**PE Bolt services configuration**

The PE Bolt server is a Ruby service that enables SSH and WinRM tasks from the console. The server accepts requests from the orchestrator, calls out to Bolt to run the task, and returns the result.

**PE Bolt server configuration**

The PE Bolt server provides an API for running tasks over SSH and WinRM using Bolt, which is the technology underlying PE tasks. The API server for tasks is available as pe-bolt-server.

The server is a Puma application that runs as a standalone service.

The server is configured in /etc/puppetlabs/bolt-server/conf.d/bolt-server.conf, managed by the puppet_enterprise::profile::bolt_server class, which includes these parameters:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Type</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>bolt_server_loglevel</td>
<td>string</td>
<td>Bolt log level. Acceptable values are debug, info, notice, warn, and error.</td>
<td>notice</td>
</tr>
<tr>
<td>concurrency</td>
<td>integer</td>
<td>Maximum number of server threads.</td>
<td>100</td>
</tr>
</tbody>
</table>
### PE ACE services configuration

The PE Agentless Catalog Executor server is a Ruby service that enables you to execute Bolt Tasks and Puppet catalogs remotely.

### PE ACE server configuration

The PE ACE server provides an API for running tasks and catalogs against remote targets.

The server is a Puma application that runs as a standalone service.

The server is configured in `/etc/puppetlabs/ace-server/conf.d/ace-server.conf`, managed by the `puppetenterprise::profile::ace_server` class, which includes these parameters:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Type</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>master_host</td>
<td>string</td>
<td>URI that ACE can access the master on.</td>
<td><code>$puppetenterprise::puppet_master_host</code></td>
</tr>
<tr>
<td>master_port</td>
<td>integer</td>
<td>Port that ACE can access the master on.</td>
<td><code>$puppetenterprise::puppet_master_port</code></td>
</tr>
<tr>
<td>hostcrl</td>
<td>string</td>
<td>The host CRL path</td>
<td><code>$puppetenterprise::params::hostcrl</code></td>
</tr>
<tr>
<td>ssl_cipher_suites</td>
<td>array[string]</td>
<td>TLS cipher suites in order of preference.</td>
<td><code>$puppetenterprise::params::secure_ciphers</code></td>
</tr>
<tr>
<td>ssl_listen_port</td>
<td>integer</td>
<td>Port that ACE runs on.</td>
<td>44633 ($puppetenterprise::ace_server_port)</td>
</tr>
<tr>
<td>whitelist</td>
<td>array[string]</td>
<td>List of hosts that can connect to pe-ace-server.</td>
<td><code>[$certname]</code></td>
</tr>
</tbody>
</table>
Disabling application management or orchestration services

Both application management and orchestration services are on by default in PE. If you need to disable these services, refer to Disabling application management and Disabling orchestration services.

Direct Puppet: a workflow for controlling change

The orchestrator—used alongside other PE tools, such as Code Manager—allows you to control when and how infrastructure changes are made before they reach your production environment.

The Direct Puppet workflow gives you precise control over rolling out changes, from updating data and classifying nodes, to deploying new Puppet code. In this workflow, you configure your agents to use cached catalogs during scheduled runs, and you send new catalogs only when you're ready, via orchestrator jobs. Scheduled runs continue to enforce the desired state of the last orchestration job until you send another new catalog.

Related information

Enable cached catalogs for use with the orchestrator (optional)

Direct Puppet workflow

In this workflow, you set up a node group for testing and validating code on a feature branch before you merge and promote it into your production environment.

Before you begin

• To use this workflow, you must enable cached catalogs for use with the orchestrator so that they enforce cached catalogs by default and compile new catalogs only when instructed to by orchestrator jobs.
• This workflow also assumes you’re familiar with Code Manager. It involves making changes to your control repo —adding or updating modules, editing manifests, or changing your Hiera data. You’ll also run deploy actions from the Code Manager command line tool and the orchestrator, so ensure you have access to a host with PE client tools installed.

Related information

Installing PE client tools on page 129
PE client tools are a set of command line tools that let you access Puppet Enterprise services from a workstation that might or might not be managed by Puppet.

Set up node groups for testing new features

The first step in the Direct Puppet workflow is to set up node groups for testing your new feature or code.

1. If they don't already exist, create environment node groups for branch testing, for example, you might create Development environment and Test environment node groups.

2. Within each of these environment node groups, create a child node group to enable on-demand testing of changes deployed in Git feature branch Puppet environments. You now have at three levels of environment node groups: 1) the top-level parent environment node group, 2) node groups that represent your actual environments, and 3) node groups specific to feature testing.

3. In the Rules tab of the child node groups you created in the previous step, add this rule:

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fact</td>
<td>agent_specified_environment</td>
</tr>
<tr>
<td>Operator</td>
<td>~</td>
</tr>
<tr>
<td>Value</td>
<td>^.+</td>
</tr>
</tbody>
</table>

This rule matches any nodes from the parent group that have the agent_specified_environment fact set. By matching nodes to this group, you give the nodes permission to override the server-specified environment and use their agent-specified environment instead.
**Related information**

Create environment node groups on page 296
Create custom environment node groups so that you can target deployment of Puppet code.

**Create a feature branch**
After you've set up a node group, create a new branch of your control repository on which you can make changes to your feature code.

1. Branch your control repository, and name the new branch, for example, *my_feature_branch*.

   ![Diagram](image)

2. Make changes to the code on your feature branch. Commit and push the changes to the *my_feature_branch*.

**Deploy code to the Puppet master and test it**
Now that you've made some changes to the code on your feature branch, you're ready to use Code Manager to push those to the Puppet master.

1. To deploy the feature branch to the master, run the following Code Manager command: `puppet code deploy --wait my_feature_branch`

   ![Diagram](image)

   **Note:** After this code deployment, there is a short delay while Puppet Server loads the new code.

2. To test your changes, run Puppet on a few agent-specified development nodes in the *my_feature_branch* environment. run the following orchestrator command:

   ```
puppet job run --nodes my-dev-node1,my-dev-node2 --environment my_feature_branch
   ```

   **Tip:** You can also use the console to create a job targeted at a list of nodes in the *my_feature_branch* environment.

3. Validate your testing changes. Open the links in the orchestrator command output, or use the Job ID linked on the Job list page, to review the node run reports in the console. Ensure the changes have the effect you intend.
Related information
Run Puppet on a node list on page 441
Create a node list target for a job when you need to run Puppet on a specific set of nodes that isn't easily defined by a PQL query.

Merge and promote your code
If everything works as expected on the development nodes, and you're ready to promote your changes into production.

1. Merge my_feature_branch into the production branch in your control repo.

2. To deploy your updated production branch to the Puppet master, run the following Code Manager command:
   puppet code deploy --wait production

Preview the job
Before running Puppet across the production environment, preview the job with the puppet job plan command.

To ensure the job captures all the nodes in the production environment, as well as the agent-specified development nodes that just ran with the my_feature_branch environment, use the following query as the job target:

```
puppet job plan --query 'inventory {environment in ["production", "my_feature_branch"]}'
```

Run the job on the production environment
If you're satisfied with the changes in the preview, you're ready to enforce changes to the production environment.

Run the orchestrator job.

```
puppet job run --query 'inventory {environment in ["production", "my_feature_branch"]}'
```

Tip: You can also use the console to create a job targeted at this PQL query.

Related information
Run Puppet on a PQL query on page 442
For some jobs, you might want to target nodes that meet specific conditions. For such jobs, create a PQL query.

**Validate your production changes**
Finally, you're ready to validate your production changes.
Check the node run reports in the console to confirm that the changes were applied as intended. If so, you're done!
Repeat this process as you develop and promote your code.

**Running Puppet on demand**
The orchestrator gives you the ability to set up jobs in the console or on the command line to trigger on-demand Puppet runs.

- **Running Puppet on demand from the console** on page 441
  When you set up a job to run Puppet from the console, the orchestrator creates a job ID to track the job, shows you all nodes included in the job, and runs Puppet on those nodes in the appropriate order. Puppet compiles a new catalog for each node included in the job.

- **Running Puppet on demand from the CLI** on page 447
  Use the `puppet job run` command to enforce change on your agent nodes with on-demand Puppet runs.

- **Running Puppet on demand with the API** on page 455
  Run the orchestrator across all nodes in an environment.

**Running Puppet on demand from the console**
When you set up a job to run Puppet from the console, the orchestrator creates a job ID to track the job, shows you all nodes included in the job, and runs Puppet on those nodes in the appropriate order. Puppet compiles a new catalog for each node included in the job.

There are two ways to specify the job target (the nodes you want to run jobs on):

- A static node list
- A Puppet Query Language (PQL) query
- A node group

You can't combine these methods, and if you switch from one to the other with the **Inventory** drop-down list, the target list clears and starts over. In other words, if you create a target list by using a node list, switching to a PQL query clears the node list, and vice versa. You can do a one-time conversion of a PQL query to a static node list if you want to add or remove nodes from the query results.

Before you start, be sure you have the correct permissions for running jobs. To run jobs on PQL queries, you need the "View node data from PuppetDB" permission.

**Run Puppet on a node list**
Create a node list target for a job when you need to run Puppet on a specific set of nodes that isn't easily defined by a PQL query.

**Before you begin**
Make sure you have access to the nodes you want to target.
Make sure you have permissions to run jobs and PQL queries.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.

1. In the console, on the **Jobs** page, click **Run Puppet**.
2. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.
3. Optional: Under Schedule, select Later and choose a start date, time, time zone, and frequency for the job to run.

   Tip: Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

4. Select an environment:
   - **Run nodes in their own assigned environment**: Nodes run in the environment specified by the Node Manager or their puppet.conf file.
   - **Select an environment for nodes to run in**: Select an environment from the list. Nodes can run in an environment if their environment is agent-specified, if they're included in an application in that environment, or if they're classified in that environment by the node manager.

   Note: If your job target includes application instances, the selected environment also determines the dependency order of your node runs.

5. Select the run mode for the job. The default run mode for a job always attempts to enforce new catalogs on nodes.
   To change the run mode, use the following selections:
   - **No-op**: Simulate a Puppet run on all nodes in the job without enforcing a new catalog.
   - **Debug**: Print all debugging messages.
   - **Trace**: Print stack traces on some errors.
   - **Eval-trace**: Display how long it took for each step to run.
   - **Override noop = true configuration**: If any nodes in the job have `noop = true` set in their puppet.conf files, Puppet ignores that setting and enforce a new catalog on those nodes. This setting corresponds to the `--no-noop` flag available on the orchestrator CLI.

6. In the Inventory list, select Node list.

7. To create a node list, in the search field, start typing in the names of nodes to search for, and click Search.

   Note: The search does not handle regular expressions.

8. Select the nodes you want to add to the job. You can select nodes from multiple searches to create the node list target.

9. Click Run job.
   View the job status and a list of previous Puppet jobs on the Jobs page.

**Run Puppet on a PQL query**

For some jobs, you might want to target nodes that meet specific conditions. For such jobs, create a PQL query.

**Before you begin**

Make sure you have access to the nodes you want to target.

Make sure you have permissions to run jobs and PQL queries.

1. In the console, on the Jobs page, click Run Puppet.

2. Optional: In the Job description field, provide a description. The text you enter here appears on the job list and job details pages.

3. Optional: Under Schedule, select Later and choose a start date, time, time zone, and frequency for the job to run.

   Tip: Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.
4. Select an environment:
   - **Run nodes in their own assigned environment**: Nodes run in the environment specified by the Node Manager or their puppet.conf file.
   - **Select an environment for nodes to run in**: Select an environment from the list. Nodes can run in an environment if their environment is agent-specified, if they're included in an application in that environment, or if they're classified in that environment by the node manager.

   **Note**: If your job target includes application instances, the selected environment also determines the dependency order of your node runs.

5. Select the run mode for the job. The default run mode for a job always attempts to enforce new catalogs on nodes. To change the run mode, use the following selections:
   - **No-op**: Simulate a Puppet run on all nodes in the job without enforcing a new catalog.
   - **Debug**: Print all debugging messages.
   - **Trace**: Print stack traces on some errors.
   - **Eval-trace**: Display how long it took for each step to run.
   - **Override noop = true configuration**: If any nodes in the job have `noop = true` set in their puppet.conf files, Puppet ignores that setting and enforce a new catalog on those nodes. This setting corresponds to the `--no-noop` flag available on the orchestrator CLI.

6. From the list of target types, select **PQL query**.

7. Specify a target by doing one of the following:
   - Enter a query that selects the target you want. See the Puppet Query Language (PQL) reference for more information.
   - Click **Common queries**. Select one of the queries and replace the defaults in the braces ({} ) with values that specify the target you want.

   **Note**: These queries include [certname] as [<projection>] to restrict the output.

<table>
<thead>
<tr>
<th>Target</th>
<th>PQL query</th>
</tr>
</thead>
<tbody>
<tr>
<td>All nodes</td>
<td>nodes[certname] ( )</td>
</tr>
<tr>
<td>Nodes with a specific resource (example: httpd)</td>
<td>resources[certname] ( type = &quot;Service&quot; and title = &quot;httpd&quot; )</td>
</tr>
<tr>
<td>Nodes with a specific fact and value (example: OS name is CentOS)</td>
<td>inventory[certname] ( facts.os.name = &quot;&lt;OS&gt;&quot; )</td>
</tr>
<tr>
<td>Nodes with a specific report status (example: last run failed)</td>
<td>reports[certname] ( latest_report_status = &quot;failed&quot; )</td>
</tr>
<tr>
<td>Nodes with a specific class (example: Apache)</td>
<td>resources[certname] ( type = &quot;Class&quot; and title = &quot;Apache&quot; )</td>
</tr>
<tr>
<td>Nodes assigned to a specific environment (example: production)</td>
<td>nodes[certname] ( catalog_environment = &quot;production&quot; )</td>
</tr>
<tr>
<td>Nodes with a specific version of a resource type (example: OpenSSL is v1.1.0e)</td>
<td>resources[certname] (type = &quot;Package&quot; and title=&quot;openssl&quot; and parameters.ensure = &quot;1.0.1e-51.el7_2.7&quot; )</td>
</tr>
<tr>
<td>Nodes with a specific resource and operating system (example: httpd and CentOS)</td>
<td>inventory[certname] ( facts.operatingsystem = &quot;CentOS&quot; and resources { type = &quot;Service&quot; and title = &quot;httpd&quot; } )</td>
</tr>
</tbody>
</table>

8. Click **Submit query** and click **Refresh** to update the node results.
9. If you change or edit the query after it runs, click **Submit query** again.

10. Optional: To convert the PQL query target results to a node list, for use as a node list target, click **Convert query to static node list**.

    **Note:** If you select this option, the job target becomes a node list. You can add or remove nodes from the node list before running the job, but you cannot edit the query.

11. Click **Run job**.

    View the job status and a list of previous Puppet jobs on the **Jobs** page.

    **Important:** When you run this job, the PQL query runs again, and the job might run on a different set of nodes than what is currently displayed. If you want the job to run only on the list as displayed, convert the query to a static node list before you run the job.

**Add custom PQL queries to the console**

Add your own PQL queries to the console and quickly access them when running jobs.

1. On your Master, as root, copy the `custom_pql_queries.json.example` file and remove the example suffix.

   ```bash
cp /etc/puppetlabs/console-services/custom_pql_queries.json.example /etc/puppetlabs/console-services/custom_pql_queries.json
   ```

2. Edit the file contents to include your own PQL queries or remove any existing queries.

3. Refresh the console UI in your browser.

You can now see your custom queries in the PQL drop down options when running jobs.

**Run Puppet on a node group**

Create a node target for a job when you need to run Puppet on a specific set of nodes in a pre-defined group.

**Before you begin**

Make sure you have access to the nodes you want to target.

**Note:** If you do not have permissions to view a node group, or the node group doesn't have any matching nodes, that node group won't be listed as an option for viewing. In addition, a node group does not appear if no rules have been specified for it.

1. In the console, on the **Jobs** page, click **Run Puppet**.

2. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.

3. Optional: Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

4. Select an environment:

   - **Run nodes in their own assigned environment:** Nodes run in the environment specified by the Node Manager or their `puppet.conf` file.
   - **Select an environment for nodes to run in:** Select an environment from the list. Nodes can run in an environment if their environment is agent-specified, if they're included in an application in that environment, or if they're classified in that environment by the node manager.

   **Note:** If your job target includes application instances, the selected environment also determines the dependency order of your node runs.
5. Select the run mode for the job. The default run mode for a job always attempts to enforce new catalogs on nodes. To change the run mode, use the following selections:

   - **No-op**: Simulate a Puppet run on all nodes in the job without enforcing a new catalog.
   - **Debug**: Print all debugging messages.
   - **Trace**: Print stack traces on some errors.
   - **Eval-trace**: Display how long it took for each step to run.
   - **Override noop = true configuration**: If any nodes in the job have `noop = true` set in their `puppet.conf` files, Puppet ignores that setting and enforce a new catalog on those nodes. This setting corresponds to the `--no-noop` flag available on the orchestrator CLI.

6. From the list of target types, select **Node group**.
7. In the **Choose a node group** box, type or select a node group, and click **Select**.
8. Click **Run job**.
   View the job status and a list of previous Puppet jobs on the **Jobs** page.

**Run jobs throughout the console**
You don't need to be in the Jobs section of the console to run a Puppet job on your nodes. You might encounter situations where you want to run jobs on lists of nodes derived from different pages in the console.

You can create jobs from the following pages:

<table>
<thead>
<tr>
<th>Page</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overview</td>
<td>This page shows a list of all your managed nodes, and gathers essential information about your infrastructure at a glance.</td>
</tr>
<tr>
<td>Events</td>
<td>Events let you view a summary of activity in your infrastructure, analyze the details of important changes, and investigate common causes behind related events. For instance, let's say you notice run failures because some nodes have out-of-date code. After you update the code, you can create a job target from the list of failed nodes to be sure you're directing the right fix to the right nodes. You can create new jobs from the <strong>Nodes with events</strong> category.</td>
</tr>
<tr>
<td>Classification node groups</td>
<td>Node groups are used to automate classification of nodes with similar functions in your infrastructure. If you make a classification change to a node group, you can quickly create a job to run Puppet on all the nodes in that group, pushing the change to all nodes at one time.</td>
</tr>
</tbody>
</table>

Make sure you have permissions to run jobs and PQL queries.

1. In the console, in the **Run** section, click **Puppet**.
   At this point, the list of nodes is converted to a new Puppet run job list target.
2. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.
3. Select an environment:
   - **Run nodes in their own assigned environment**: Nodes run in the environment specified by the Node Manager or their puppet.conf file.
   - **Select an environment for nodes to run in**: Select an environment from the list. Nodes can run in an environment if their environment is agent-specified, if they're included in an application in that environment, or if they're classified in that environment by the node manager.

   **Note**: If your job target includes application instances, the selected environment also determines the dependency order of your node runs.

4. Select the run mode for the job. The default run mode for a job always attempts to enforce new catalogs on nodes. To change the run mode, use the following selections:
   - **No-op**: Simulate a Puppet run on all nodes in the job without enforcing a new catalog.
   - **Debug**: Print all debugging messages.
   - **Trace**: Print stack traces on some errors.
   - **Eval-trace**: Display how long it took for each step to run.
   - **Override noop = true configuration**: If any nodes in the job have `noop = true` set in their puppet.conf files, Puppet ignores that setting and enforce a new catalog on those nodes. This setting corresponds to the `--no-noop` flag available on the orchestrator CLI.

5. **Important**: Do not change the Inventory from **Node list** to **PQL query**. This clears the node list target.

6. Click **Run job**. View the job status and a list of previous Puppet jobs on the **Jobs** page.

**Schedule a Puppet run**
Schedule a job to deploy configuration changes at a particular date and time.

**Before you begin**
Make sure you have access to the nodes you want to target.

1. In the console, on the **Jobs** page, click **Run Puppet**.
2. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.
3. Select an environment:
   - **Run nodes in their own assigned environment**: Nodes run in the environment specified by the Node Manager or their puppet.conf file.
   - **Select an environment for nodes to run in**: Select an environment from the list. Nodes can run in an environment if their environment is agent-specified, if they're included in an application in that environment, or if they're classified in that environment by the node manager.

   **Note**: If your job target includes application instances, the selected environment also determines the dependency order of your node runs.

4. Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip**: Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

5. Optional: To repeat the job on a regular schedule, change the run frequency from **Once** to **Hourly**, **Daily**, or **Weekly**.

   **Note**: If a recurring job runs longer than the selected frequency, the following job waits to start until the next available time interval.

© 2020 Puppet, Inc.
6. Select the run mode for the job. The default run mode for a job always attempts to enforce new catalogs on nodes. To change the run mode, use the following selections:
   - **No-op**: Simulate a Puppet run on all nodes in the job without enforcing a new catalog.
   - **Debug**: Print all debugging messages.
   - **Trace**: Print stack traces on some errors.
   - **Eval-trace**: Display how long it took for each step to run.
   - **Override noop = true configuration**: If any nodes in the job have `noop = true` set in their `puppet.conf` files, Puppet ignores that setting and enforce a new catalog on those nodes. This setting corresponds to the `--no-noop` flag available on the orchestrator CLI.

7. From the list of target types, select the category of nodes you want to target.
   - **Node list**: Add individual nodes by name.
   - **PQL Query**: Use the Puppet query language to retrieve a list of nodes.
   - **Node group**: Select an existing node group.

8. Click **Schedule job**.
   Your job appears on the **Scheduled Puppet run** tab of the **Jobs** page.

**Stop a job in progress**
You can stop a job if, for example, you realize you need to reconfigure a class or push a configuration change that the job needs.

When you stop an on-demand Puppet run, runs that are underway finish, and runs that have not started are canceled.

To stop a job:
   - In the console, go to the **Jobs** page and select the **Puppet run** tab. From the list of jobs, find the one you want and click **Stop**.
   - On the command line, press **CTRL + C**.

**Delete a scheduled job**
Delete a job that is scheduled to run at a later time.

**Tip**: You must have the appropriate role-based permissions to delete another user's scheduled job.
   1. In the console, open the **Jobs** page.
   2. Click the **Scheduled Puppet Run** tab.
   3. From the list of jobs, find the one you want to delete and click **Remove**.

**Running Puppet on demand from the CLI**
Use the **puppet job run** command to enforce change on your agent nodes with on-demand Puppet runs.

Use the **puppet job** tool to enforce change across nodes. For example, when you add a new class parameter to a set of nodes or deploy code to a new Puppet environment, use this command to run Puppet across all the nodes in that environment.

If you run a job on a node that has relationships outside of the target (for example, it participates in an application that includes nodes not in the job target) the job still runs only on the node in the target you specified. In such cases, the orchestrator notifies you that external relationships exist. It prints the node with relationships, and it prints the applications that might be affected. For example:

**WARNING** target does not contain all nodes in this application.

You can run jobs on three types of targets, but these targets cannot be combined:
   - An application or an application instance in an environment
   - A list of nodes or a single node
   - A PQL nodes query
When you execute a `puppet job run` command, the orchestrator creates a new Job ID, shows you all nodes included in the job, and proceeds to run Puppet on all nodes in the appropriate order. Puppet compiles a new catalog for all nodes included in the job.

The orchestrator command line tool includes the `puppet job` and `puppet app` commands.

- **puppet job**
  
  The `puppet job` command is the main mechanism to control Puppet jobs. For a complete reference of the `puppet job` command, see:
  
  - Checking job plans on the CLI
  - Running jobs on the CLI
  - Reviewing jobs on the CLI

- **puppet app**
  
  The `puppet app` tool lets you view the application models and application instances you’ve written and stored on your Puppet master. For a complete reference of the `puppet app` command, see Reviewing applications on the CLI.

**Run Puppet on a PQL query**

Use a PQL nodes query as a target when you want to target nodes that meet specific conditions. In this case, the orchestrator runs on a list of nodes returned from a PQL nodes query.

**Before you begin**

The first time you run a command, you need to authenticate. See the orchestrator installation instructions for information about setting RBAC permissions and token authorization.

If you’re running this command from a managed or non-managed Windows workstation, you must specify the full path to the command. For example, `c:\Program Files\Puppet Labs\Client\bin\puppet-task run`.

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.

Make sure you have permissions to run tasks and PQL queries.

Make sure you have permissions to run jobs and PQL queries.

Make sure you have permissions to run jobs and PQL queries.

Log into your Puppet master or client tools workstation and run one of the following commands:

- To specify the query on the command line: `puppet job run --query '<QUERY>' <OPTIONS>`
- To pass the query in a text file: `puppet job run --query @/path/to/file.txt`

The following table shows some example targets and the associated PQL queries you could run with the orchestrator.

Be sure to wrap the entire query in single quotes and use double quotes inside the query.

<table>
<thead>
<tr>
<th>Target</th>
<th>PQL query</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single node by certname</td>
<td><code>--query 'nodes { certname = &quot;mynode&quot; }'</code></td>
</tr>
<tr>
<td>All nodes with &quot;web&quot; in certname</td>
<td><code>--query 'nodes { certname ~ &quot;web&quot; }'</code></td>
</tr>
<tr>
<td>Target</td>
<td>PQL query</td>
</tr>
<tr>
<td>--------</td>
<td>-----------</td>
</tr>
<tr>
<td>All CentOS nodes</td>
<td><code>--query 'inventory { facts.os.name = &quot;CentOS&quot; }'</code></td>
</tr>
<tr>
<td>All CentOS nodes with httpd managed</td>
<td><code>--query 'inventory { facts.operatingsystem = &quot;CentOS&quot; and resources { type = &quot;Service&quot; and title = &quot;httpd&quot; } }'</code></td>
</tr>
<tr>
<td>All nodes with failed reports</td>
<td><code>--query 'reports { latest_report? = true and status = &quot;failed&quot; }'</code></td>
</tr>
<tr>
<td>All nodes matching the environment for the last received catalog</td>
<td><code>--query 'nodes { catalog_environment = &quot;production&quot; }'</code></td>
</tr>
</tbody>
</table>

To view the status of the Puppet job, run `puppet job show <job ID>`. To view a list of the previous 50 running and complete Puppet jobs, run `puppet job show`.

**Run Puppet on a list of nodes or a single node**

Use a node list target for an orchestrator job when you need to run a job on a specific set of nodes that don't easily resolve to a PQL query. Use a single node or a comma-separated list of nodes.

**Before you begin**

The first time you run a command, you need to authenticate. See the orchestrator installation instructions for information about setting RBAC permissions and token authorization.

If you're running this command from a managed or non-managed Windows workstation, you must specify the full path to the command. For example, `c:\Program Files\Puppet Labs\Client\bin\puppet-task run`.

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.

Make sure you have permissions to run tasks and PQL queries.

Make sure you have permissions to run jobs and PQL queries.

Log into your Puppet master or client tools workstation and run one of the following commands:

- To run a job on a single node:
  
  `puppet job run --nodes <NODE NAME> <OPTIONS>`

- To run a job on a list of nodes, use a **comma-separated** list of node names:
  
  `puppet job run --nodes <NODE NAME>,<NODE NAME>,<NODE NAME>,<NODE NAME> <OPTIONS>`

  **Note:** Do not add spaces in the list of nodes.

- To run a job on a node list from a text file:
  
  `puppet job run --nodes @/path/to/file.txt`

  **Note:** If passing a list of nodes in the text file, put each node on a separate line.
To view the status of the Puppet job, run `puppet job show <job ID>`. To view a list of the previous 50 running and complete Puppet jobs, run `puppet job show`.

**Run Puppet on a node group**

Similar to running Puppet on a list of nodes, you can run it on a node group.

**Before you begin**

Make sure you have access to the nodes you want to target.

1. Log into your master or client tools workstation.
2. Run the command: `puppet job run --node-group <node-group-id>`
   
   **Tip:** Use the `/v1/groups` endpoint to retrieve a list node groups and their IDs.

**Related information**

GET `/v1/groups` on page 361

Use the `/v1/groups` endpoint to retrieve a list of all node groups in the node classifier.

**Run Puppet on an application or an application instance in an environment**

Use applications as a job target to enforce Puppet runs in order on all nodes found in a specific application instance, or to enforce Puppet runs in order on all nodes that are found in each instance of an application.

**Before you begin**

The first time you run a command, you need to authenticate. See the [orchestrator installation instructions](#) for information about setting RBAC permissions and token authorization.

If you're running this command from a managed or non-managed Windows workstation, you must specify the full path to the command. For example, `c:\Program Files\Puppet Labs\Client\bin\puppet-task run`.

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in [Puppet Forge](#).

Make sure you have permissions to run tasks and PQL queries.

Make sure you have permissions to run jobs and PQL queries.

Log into your Puppet master or client tools workstation and run one of the following commands:

- To run a job on all instances of an application: `puppet job run --application <APPLICATION> --environment <ENVIRONMENT>`
- To run a job on an instance of an application in an environment: `puppet job run --application <APPLICATION INSTANCE> --environment <ENVIRONMENT>`

**Tip:** You can use `-a` in place of `--application`.

To view the status of the Puppet job, run `puppet job show <job ID>`. To view a list of the previous 50 running and complete Puppet jobs, run `puppet job show`.
**puppet job run command options**

The following are common options you can use with the `run` action. For a complete list of global options run `puppet job --help`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--noop</code></td>
<td>Flag, default false</td>
<td>Run a job on all nodes to simulate changes from a new catalog without actually enforcing a new catalog. Cannot be used in conjunction with <code>--no-noop</code> flag.</td>
</tr>
<tr>
<td><code>--no-nopp</code></td>
<td>Flag</td>
<td>All nodes run in enforcement mode, and a new catalog is enforced on all nodes. This flag overrides the agent <code>noop = true</code> in <code>puppet.conf</code>. Cannot be used in conjunction with <code>--noop</code> flag.</td>
</tr>
<tr>
<td><code>--environment, -e</code></td>
<td>Environment name</td>
<td>Overrides the environment specified in the orchestrator configuration file. The orchestrator uses this option to:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Instruct nodes what environment to run in. If any nodes can’t run in the environment, those node runs fail. A node runs in an environment if:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The node is included in an application in that environment. These runs may fail if the node is classified into a different environment in the PE node classifier.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The node is classified into that environment in the PE node classifier.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Load the application code used to plan run order</td>
</tr>
<tr>
<td><code>--no-enforce-environment</code></td>
<td>Flag, default false</td>
<td>Ignores the environment set by the <code>--environment</code> flag for agent runs. When you use this flag, agents run in the environment specified by the PE Node Manager or their <code>puppet.conf</code> files.</td>
</tr>
<tr>
<td><code>--description</code></td>
<td>Flag, defaults to empty</td>
<td>Provide a description for the job, to be shown on the job list and job details pages, and returned with the <code>puppet job show</code> command.</td>
</tr>
<tr>
<td><code>--concurrency</code></td>
<td>Integer</td>
<td>Limits how many nodes can run concurrently. Default is unlimited. You can tune concurrent compile requests in the console.</td>
</tr>
</tbody>
</table>
Post-run node status
After Puppet runs, the orchestrator returns a list of nodes and their run statuses.

Node runs can be in progress, completed, skipped, or failed.

- For a completed node run, the orchestrator prints the configuration version, the transaction ID, a summary of resource events, and a link to the full node run report in the console.
- For an in progress node run, the orchestrator prints how many seconds ago the run started.
- For a failed node run, the orchestrator prints an error message indicating why the run failed. In this case, any additional runs are skipped.

When a run fails, the orchestrator also prints any applications that were affected by the failure, as well as any applications that were affected by skipped node runs.

You can view the status of all running, completed, and failed jobs with the `puppet job show` command, or you can view them from the Job details page in the console.

Additionally, on the Jobs page in the console, you can review a list of jobs or to view the details of jobs that have previously run or are in progress.

Stop a job in progress
You can stop a job if, for example, you realize you need to reconfigure a class or push a configuration change that the job needs.

When you stop an on-demand Puppet run, runs that are underway finish, and runs that have not started are canceled.

To stop a job:
- In the console, go to the Jobs page and select the Puppet run tab. From the list of jobs, find the one you want and click Stop.
- On the command line, press CTRL + C.

Viewing job plans
The `puppet job plan` command allows you to preview a plan for a Puppet job without actually enforcing any change. Use this command to ensure your job runs as expected.

You can preview plans for three types of targets, but these targets cannot be combined:

- View a plan to enforce change on a list of nodes or a single node
- View a plan to enforce change based on a PQL nodes query
- View a plan to enforce change on an application or an application instance in an environment

Results from the job plan command
The `puppet job plan` command returns the following about a job:

- The environment the job runs in.
- The target for the job.
- The maximum concurrency setting for the job.
- The total number of nodes in the job run.
- A list of application instances included in the job, if applicable.
- A list of nodes sorted topographically, with components and application instances listed below each node. The node list is organized in levels by dependencies. Nodes shown at the top, level 0, have no dependencies. Nodes in level 1 have dependencies in level 0. A node can run after Puppet has finished running on all its dependencies.

Note: The `puppet job plan` does not generate a job ID. A job ID is created, and shown in the job plan, only when you use `puppet job run`. Use the job ID to view jobs with the `puppet job show` command.

After you view the plan:
- Use puppet job run <SAME TARGET AND OPTIONS> to create and run a job like this.
- Remember that node catalogs might have changed after this plan was generated.

© 2020 Puppet, Inc.
• Review and address any errors that the service reports. For example, it detects any dependency cycles or components that not properly mapped to nodes.

**Example job plan**
The following is an example plan summary for a job that runs on a list of nodes that contain a partial application instance.

![Image of job plan]

**View a job plan for a list of nodes or a single node**
You can view a plan for enforcing change on a single node or a comma-separated list of nodes.

**Before you begin**
The first time you run a command, you need to authenticate. See the orchestrator installation instructions for information about setting RBAC permissions and token authorization.

If you're running this command from a managed or non-managed Windows workstation, you must specify the full path to the command. For example, `c:\Program Files\Puppet Labs\Client\bin\puppet-task run`.

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.

Make sure you have permissions to run tasks and PQL queries.

Make sure you have permissions to run jobs and PQL queries.

Log into your Puppet master or client tools workstation and run one of the following commands:

- To view a plan for a single node: `puppet job plan --nodes <NODE NAME> <OPTIONS>`
- To view a plan for a list of nodes, use a **comma-separated** list of node names. `puppet job plan --nodes <NODE NAME>, <NODE NAME>, <NODE NAME>, <NODE NAME> <OPTIONS>`

**Tip:** You can use `-n` in place of `--nodes`.

**View a job plan for a PQL nodes query**
Use a PQL nodes query as a job target. In this case, the orchestrator presents a plan for a job that could run on a list of nodes returned from a PQL nodes query.

1. Ensure you have the correct permissions to use PQL queries.
2. Log into your Puppet master or client tools workstation and run the following command:
   `puppet job plan --query '<QUERY>' <OPTIONS>`

   **Tip:** You can use `-q` in place of `--query`.

   The following table shows some example targets and the associated PQL queries you could run with the orchestrator.

   Be sure to wrap the entire query in single quotes and use double quotes inside the query.

<table>
<thead>
<tr>
<th>Target</th>
<th>PQL query</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single node by certname</td>
<td><code>--query 'nodes { certname = &quot;mynode&quot; }'</code></td>
</tr>
<tr>
<td>All nodes with &quot;web&quot; in certname</td>
<td><code>--query 'nodes { certname ~ &quot;web&quot; }'</code></td>
</tr>
<tr>
<td>All CentOS nodes</td>
<td><code>--query 'inventory { facts.os.name = &quot;CentOS&quot; }'</code></td>
</tr>
<tr>
<td>All CentOS nodes with httpd managed</td>
<td><code>--query 'inventory { facts.operatingsystem = &quot;CentOS&quot; and resources { type = &quot;Service&quot; and title = &quot;httpd&quot; } }'</code></td>
</tr>
<tr>
<td>All nodes with failed reports</td>
<td><code>--query 'reports { latest_report? = true and status = &quot;failed&quot; }'</code></td>
</tr>
<tr>
<td>All nodes matching the environment for the last received catalog</td>
<td><code>--query 'nodes { catalog_environment = &quot;production&quot; }'</code></td>
</tr>
</tbody>
</table>

   **View a job plan for applications or application instances**

   You can view a plan for enforcing change on all instances of an application or for a specific instance of an application.

   Log into your Puppet master or client tools workstation and run one of the following commands:

   - To view a job plan for all instances of an application: `puppet job plan --application <APPLICATION> <OPTIONS>`
   - To view a job plan for an application instance in an environment: `puppet job plan --application <APPLICATION INSTANCE> <OPTIONS>`

   **Tip:** You can use `-a` in place of `--application`. 
**Puppet job plan command options**

The following table shows common options for the `puppet job plan` command. For a complete list of options, run `puppet job --help`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--environment</code></td>
<td>Environment name</td>
<td>Overrides the environment specified in the orchestrator configuration file.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The orchestrator uses this option to:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Instruct nodes what environment to run in. If any nodes can’t run in the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>environment, those node runs fail. A node runs in an environment if:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The node is included in an application in that environment. These runs</td>
</tr>
<tr>
<td></td>
<td></td>
<td>may fail if the node is classified into a different environment in the PE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>node classifier.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The node is classified into that environment in the PE node classifier.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Load the application code used to plan run order</td>
</tr>
<tr>
<td><code>--concurrency</code></td>
<td>Integer</td>
<td>Limits how many nodes can run concurrently. Default is unlimited. You can</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tune concurrent compile requests in the console.</td>
</tr>
</tbody>
</table>

**POST /command/deploy**

Run the orchestrator across all nodes in an environment.

**Request format**

The request body must be a JSON object using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>The environment to deploy. <strong>This key is required.</strong></td>
</tr>
<tr>
<td>scope</td>
<td>Object, required unless <code>target</code> is specified. The PuppetDB query, a list</td>
</tr>
<tr>
<td></td>
<td>of nodes, a classifier node group id, or an application/application instance</td>
</tr>
<tr>
<td></td>
<td>to deploy.</td>
</tr>
<tr>
<td>description</td>
<td>String, a description of the job.</td>
</tr>
<tr>
<td>noop</td>
<td>Boolean, whether to run the agent in no-op mode. The default is false.</td>
</tr>
<tr>
<td>no_noop</td>
<td>Boolean, whether to run the agent in enforcement mode. Defaults to false.</td>
</tr>
<tr>
<td></td>
<td>This flag overrides <code>noop = true</code> if set in the agent's <code>puppet.conf</code>, and</td>
</tr>
<tr>
<td></td>
<td>cannot be set to true at the same time as the <code>noop</code> flag.</td>
</tr>
<tr>
<td>concurrency</td>
<td>Integer, the maximum number of nodes to run at one time. The default, if</td>
</tr>
<tr>
<td></td>
<td>unspecified, is unlimited.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enforce_environment</td>
<td>Boolean, whether to force agents to run in the same environment in which their assigned applications are defined. This key is required to be false if environment is an empty string</td>
</tr>
<tr>
<td>debug</td>
<td>Boolean, whether to use the --debug flag on Puppet agent runs.</td>
</tr>
<tr>
<td>trace</td>
<td>Boolean, whether to use the --trace flag on Puppet agent runs.</td>
</tr>
<tr>
<td>evaltrace</td>
<td>Boolean, whether to use the --evaltrace flag on Puppet agent runs.</td>
</tr>
<tr>
<td>filetimeout</td>
<td>Integer, sets the --filetimeout flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>http_connect_timeout</td>
<td>Integer, sets the --http_connect_timeout flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>http_keepalive_timeout</td>
<td>Integer, sets the --http_keepalive_timeout flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>http_read_timeout</td>
<td>Integer, sets the --http_read_timeout flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>ordering</td>
<td>String, sets the --ordering flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>skip_tags</td>
<td>String, sets the --skip_tags flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>tags</td>
<td>String, sets the --tags flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>use_cached_catalog</td>
<td>Boolean, whether to use the --use_cached_catalog flag on Puppet agent runs.</td>
</tr>
<tr>
<td>usecacheonfailure</td>
<td>Boolean, whether to use the --usecacheonfailure flag on Puppet agent runs.</td>
</tr>
<tr>
<td>target</td>
<td>String, required unless scope is specified. The name of an application or application instance to deploy. If an application is specified, all instances of that application are deployed. If this key is left blank or unspecified without a scope, the entire environment is deployed. This key is deprecated.</td>
</tr>
</tbody>
</table>

For example, to deploy the node1.example.com environment in no-op mode, the following request is valid:

```json
{
  "environment" : "",
  "noop" : true,
  "scope" : {
    "nodes" : ["node1.example.com"]
  }
}
```

**Scope**

Scope is a JSON object containing exactly one of these keys:

© 2020 Puppet, Inc.
To deploy an application instance in the production environment:

```json
{
    "environment" : "production",
    "scope" : {
        "application" : "Wordpress_app[demo]"
    }
}
```

To deploy a list of nodes:

```json
{
    "environment" : "production",
    "scope" : {
        "nodes" : ["node1.example.com", "node2.example.com"]
    }
}
```

To deploy a list of nodes with the certname value matching a regex:

```json
{
    "environment" : "production",
    "scope" : {
        "query" : ["from", "nodes", ["~", "certname", ".+"]]
    }
}
```

To deploy to the nodes defined by the "All Nodes" node group:

```json
{
    "environment" : "production",
    "scope" : {
        "node_group" : "00000000-0000-4000-8000-000000000000"
    }
}
```

**Response format**

If all node runs succeed, and the environment is successfully deployed, the server returns a 202 response.

The response is a JSON object containing a link to retrieve information about the status of the job and uses any one of these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>application</td>
<td>The name of an application or application instance to deploy. If an application type is specified, all instances of that application are deployed.</td>
</tr>
<tr>
<td>nodes</td>
<td>A list of node names to target.</td>
</tr>
<tr>
<td>query</td>
<td>A PuppetDB or PQL query to use to discover nodes. The target is built from certname values collected at the top level of the query.</td>
</tr>
<tr>
<td>node_group</td>
<td>A classifier node group ID. The ID must correspond to a node group that has defined rules. It is not sufficient for parent groups of the node group in question to define rules. The user must also have permissions to view the node group.</td>
</tr>
</tbody>
</table>
### Key Definition

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL that links to the newly created job.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the newly created job.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "job": {
        "id": "https://orchestrator.example.com:8143/orchestrator/v1/jobs/1234",
        "name": "1234"
    }
}
```

### Error responses

For this endpoint, the **kind** key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/unknown-environment</td>
<td>If the environment does not exist, the server returns a 404 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/empty-environment</td>
<td>If the environment requested contains no applications or no nodes, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/empty-target</td>
<td>If the application instance specified to deploy does not exist or is empty, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/dependency-cycle</td>
<td>If the application code contains a cycle, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/puppetdb-error</td>
<td>If the orchestrator is unable to make a query to PuppetDB, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/query-error</td>
<td>If a user does not have appropriate permissions to run a query, or if the query is invalid, the server returns a 400 response.</td>
</tr>
</tbody>
</table>

### Related information

  From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

### Tasks and plans in PE

Use the orchestrator to run tasks and plans in the console or on the command line.

You can install pre-existing tasks and plans and run them from the console and from the command line.

**Note:** If you have set up compilers and you want to use tasks and/or plans, you must either set `master_uris` or you `server_list` on agents to point to your compilers. This setting is described in the section on configuring compilers for orchestrator scale.

A **task** is a single action that you execute on target machines. With tasks, you can troubleshoot and deploy changes to individual or multiple systems in your infrastructure.
A plan is a bundle of tasks that can be combined with other logic. They allow you to do complex task operations, like running multiple tasks with one command or running certain tasks based on the output of another task.

You can run tasks and plans from your tool of choice: the console, the orchestrator command line interface (CLI), or the orchestrator API /command/task and /command/plan_run endpoints.

You can launch a task or plan and check on the status or view the output later with the console or CLI.

Running a task or plan does not update your Puppet configuration. If you run a task or plan that changes the state of a resource that Puppet is managing, a subsequent Puppet run changes the state of that resource back to what is defined in your Puppet configuration. For example, if you use a task to update the version of a managed package, the version of that package is reset to whatever is specified in a manifest on the next Puppet run.

**Note:** If you are running multiple tasks and plans, make sure your concurrency limit for tasks and bolt-server can accommodate your needs. See Configure the orchestrator and pe-orchestration-services on page 166 to adjust these settings.

### RBAC for tasks and plans

Tasks rely on role-based access control (RBAC) to determine who can run which tasks on your infrastructure. You can delegate access, even on a per-task basis, to ensure that teams or individuals can run task and plan jobs only on infrastructure they manage.

RBAC for plans and tasks do not intersect. This means that if a user does not have access to a specific task but they have access to run a plan containing that task, they are still able to run the plan. This allows you to implement more customized security options by wrapping tasks within plans. Read more about RBAC considerations for writing plans here.

- **Installing tasks and plans** on page 459
  Puppet Enterprise comes with some pre-installed tasks, but you must install all plans or any other tasks you want to use.
- **Running tasks in PE** on page 460
  Use the orchestrator to set up jobs in the console or on the command line and run Bolt tasks across systems in your infrastructure.
- **Running plans in PE** on page 472
  Use the orchestrator to set up jobs in the console or on the command line and run plans across systems in your infrastructure.

### Installing tasks and plans

Puppet Enterprise comes with some pre-installed tasks, but you must install all plans or any other tasks you want to use.

**Note:** Many of the modules that come pre-installed with the open-source Bolt tool will not be available by default in PE.

PE comes with the following tasks already installed:

- **package** - Inspect, install, upgrade, and manage packages.
- **service** - Start, stop, restart, and check the status of a service.
- **facter_task** - Inspect the value of system facts.
- **puppet_conf** - Inspect Puppet agent configuration settings.

Tasks and plans are packaged in Puppet modules.

Tasks can be installed from the Forge and managed with a Puppetfile and Code Manager.

Plans must be installed using Code Manager. See Plan caveats and limitations on page 474 for information about code deployment for plans.

Additional modules that include helpful task and plan content include:

- **puppet_agent**: Install Puppet Agent package.
• **reboot**: Manage system reboots.

**Related information**

- [Managing environment content with a Puppetfile](page 583)
  
  A Puppetfile specifies detailed information about each environment's Puppet code and data, including where to get that code and data from, where to install it, and whether to update it.

---

**Running tasks in PE**

Use the orchestrator to set up jobs in the console or on the command line and run Bolt tasks across systems in your infrastructure.

**Note**: If you have set up compilers and you want to use tasks, you must either set `master.uris` or `server.list` on agents to point to your compilers. This setting is described in the section on configuring compilers for orchestrator scale.

  Run ad-hoc tasks on target machines to upgrade packages, restart services, or perform any other type of single-action executions on your nodes.

- [Running tasks from the command line](page 466)
  
  Use the `puppet task run` command to run tasks on agent nodes.

- [Scheduling tasks](page 471)
  
  When you run tasks in the console, you have the option to schedule a recurring task, schedule a task for later, or delete a scheduled task.

**Related information**

- [Configure compilers](page 128)
  
  Compilers must be configured to appropriately route communication between your master and agent nodes.

---

**Running tasks from the console**

Run ad-hoc tasks on target machines to upgrade packages, restart services, or perform any other type of single-action executions on your nodes.

When you set up a job to run a task from the console, the orchestrator creates a job ID to track the job, shows you all nodes included in the job, and runs the tasks on those nodes in the appropriate order. Puppet compiles a new catalog for each node included in the job.

There are three ways to specify the job target (the nodes you want to run tasks on):

- A static node list
- A Puppet Query Language (PQL) query
- A node group

You can't combine these methods, and if you switch from one to the other, the target list clears and starts over. In other words, if you create a target list by using a node list, switching to a PQL query clears the node list. You can do a one-time conversion of a PQL query to a static node list if you want to add or remove nodes from the query results.

**Important**: Running a task does not update your Puppet configuration. If you run a task that changes the state of a resource that Puppet is managing (such as upgrading a service or package), a subsequent Puppet run changes the state of that resource back to what is defined in your Puppet configuration. For example, if you use a task to update the version of a managed package, the version of that package is reset to whatever is specified in the relevant manifest on the next Puppet run.

**Run a task on a node list**

Create a list of target nodes when you need to run a task on a specific set of nodes that isn't easily defined by a PQL query.

**Before you begin**

Install the tasks you want to use.

Make sure you have permission to run the tasks.
Make sure you have access to the nodes you want to target.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.

1. In the console, in the Orchestrations section, click **Tasks**.
2. Click **Run a task** in the upper right corner of the **Tasks** page.
3. In the **Code environment** field, select the environment where you installed the module containing the task you want to run. This defaults to **production**.
4. In the **Task** field, select a task to run, for example **service**.
   
   **Note:** If the tasks you expect are not available, you either have no tasks installed, or you don't have the correct permissions to run them.
5. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.
6. Under **Task parameters**, add optional parameters and enter values for the optional and required parameters on the list.
   
   **Important:** You must click **Add parameter** for each optional parameter-value pair you add to the task.

   To view information about required and optional parameters for the task, select **view task metadata** below the **Task** field.

   Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (**"**). Structured values, like an array, must be valid JSON.

   Tasks with default values run using the default value unless another value is specified.

   **Note:** The parameters you supplied the first time you ran a task will be used for subsequent tasks run when using the **Run again** feature on the **Task details** page.
7. Optional: Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.
8. From the list of target types, select **Node list**.
9. Create the node list.
   
   a) Expand the **Inventory nodes** target.
   b) Enter the name of the node you want to find and click **Search**.

      **Note:** The search does not handle regular expressions but does support partial matches.
   c) From the list of results, select the nodes that you want to add to your list. They are added to a table below.
   d) Repeat the search to add other nodes. You can select nodes from multiple searches to create the node list.

   **Tip:** To remove a node from the table, select the checkbox next to it and click **Remove selected**.
10. Click **Run task** or **Schedule job**.

    Your task run appears on the **Tasks** page. Click the **ID** number to view the results and output.

    **Tip:** Filter run results by task name to find specific task runs.

**Run a task over SSH**

Use the SSH protocol to run tasks on target nodes that do not have the Puppet agent installed.

**Before you begin**

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

1. In the console, in the **Orchestrations** section, click **Tasks**.
2. Click **Run a task** in the upper right corner of the **Tasks** page.

© 2020 Puppet, Inc.
3. In the **Code environment** field, select the environment where you installed the module containing the task you want to run. This defaults to **production**.

4. In the **Task** field, select a task to run, for example **service**.

   **Note:** If the tasks you expect are not available, you either have no tasks installed, or you don't have the correct permissions to run them.

5. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.

6. Under **Task parameters**, add optional parameters and enter values for the optional and required parameters on the list.

   **Important:** You must click **Add parameter** for each optional parameter-value pair you add to the task.

   To view information about required and optional parameters for the task, select **view task metadata** below the **Task** field.

   Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (" "). Structured values, like an array, must be valid JSON.

   **Tasks with default values run using the default value unless another value is specified.**

   **Note:** The parameters you supplied the first time you ran a task will be used for subsequent tasks run when using the **Run again** feature on the **Task details** page.

7. Optional: Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

8. From the list of target types, select **Node list**.

9. Create the node list.

   a) Expand the **SSH nodes** target.

   **Note:** This target is available only for tasks permitted to run on all nodes.

   b) Enter the target host names and the credentials required to access them. If you use an SSH key, include begin and end tags.

   c) Optional: Select additional target options.

      For example, to add a target port number, select **Target port** from the drop-down list, enter the number, and click **Add**.

   d) Click **Add nodes**. They are added to a table below.

   e) Repeat these steps to add other nodes. You can add SSH nodes with different credentials to create the node list.

   **Tip:** To remove a node from the table, select the checkbox next to it and click **Remove selected**.

10. Click **Run task** or **Schedule job**.

    Your task run appears on the **Tasks** page. Click the **ID** number to view the results and output.

    **Tip:** Filter run results by task name to find specific task runs.

**Run a task over WinRM**

Use the Windows Remote Management (WinRM) to run tasks on target nodes that do not have the Puppet agent installed.

**Before you begin**

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

1. In the console, in the **Orchestration** section, click **Tasks**.

2. Click **Run a task** in the upper right corner of the **Tasks** page.
3. In the **Code environment** field, select the environment where you installed the module containing the task you want to run. This defaults to **production**.

4. In the **Task** field, select a task to run, for example **service**.
   
   **Note:** If the tasks you expect are not available, you either have no tasks installed, or you don't have the correct permissions to run them.

5. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.

6. Under **Task parameters**, add optional parameters and enter values for the optional and required parameters on the list.
   
   **Important:** You must click **Add parameter** for each optional parameter-value pair you add to the task.

   To view information about required and optional parameters for the task, select **view task metadata** below the **Task** field.

   Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (" "). Structured values, like an array, must be valid JSON.

   Tasks with default values run using the default value unless another value is specified.

   **Note:** The parameters you supplied the first time you ran a task will be used for subsequent tasks run when using the **Run again** feature on the **Task details** page.

7. Optional: Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

8. From the list of target types, select **Node list**.

9. Create the node list.
   
   a) Expand the **WinRM nodes** target.

   **Note:** This target is available only for tasks permitted to run on all nodes.
   
   b) Enter the target host names and the credentials required to access them.
   
   c) Optional: Select additional target options.

   For example, to add a target port number, select **Target Port** from the drop-down list, enter the number, and click **Add**.
   
   d) Click **Add nodes**. They are added to a table below.
   
   e) Repeat these steps to add other nodes. You can add nodes with different credentials to create the node list.

   **Tip:** To remove a node from the table, select the checkbox next to it and click **Remove selected**.

10. Click **Run task** or **Schedule job**.

    Your task run appears on the **Tasks** page. Click the ID number to view the results and output.

    **Tip:** Filter run results by task name to find specific task runs.

**Run a task on a PQL query**

Create a PQL query to run tasks on nodes that meet specific conditions.

**Before you begin**

Install the tasks you want to use.

Make sure you have access to the nodes you want to target.

Make sure you have permissions to run tasks and PQL queries.

1. In the console, in the **Orchestration** section, click **Tasks**.

2. Click **Run a task** in the upper right corner of the **Tasks** page.

3. In the **Code environment** field, select the environment where you installed the module containing the task you want to run. This defaults to **production**.
4. In the **Task** field, select a task to run, for example *service*.

   **Note:** If the tasks you expect are not available, you either have no tasks installed, or you don't have the correct permissions to run them.

5. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.

6. Under **Task parameters**, add optional parameters and enter values for the optional and required parameters on the list.

   **Important:** You must click **Add parameter** for each optional parameter-value pair you add to the task.

   To view information about required and optional parameters for the task, select **view task metadata** below the **Task** field.

   Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (""). Structured values, like an array, must be valid JSON.

   Tasks with default values run using the default value unless another value is specified.

   **Note:** The parameters you supplied the first time you ran a task will be used for subsequent tasks run when using the **Run again** feature on the **Task details** page.

7. Optional: Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

8. From the list of target types, select **PQL query**.

9. Specify a target by doing one of the following:

   - Enter a query that selects the target you want. See the [Puppet Query Language (PQL) reference](https://puppet.com/docs/puppet/6/puppet-query-language.html) for more information.
   - Click **Common queries**. Select one of the queries and replace the defaults in the braces ({{ }}) with values that specify the target you want.

<table>
<thead>
<tr>
<th>Target</th>
<th>PQL query</th>
</tr>
</thead>
<tbody>
<tr>
<td>All nodes</td>
<td>nodes[certname] ( )</td>
</tr>
<tr>
<td>Nodes with a specific resource (example: httpd)</td>
<td>resources[certname] { type = &quot;Service&quot; and title = &quot;httpd&quot; }</td>
</tr>
<tr>
<td>Nodes with a specific fact and value (example: OS name is CentOS)</td>
<td>inventory[certname] { facts.os.name = &quot;&lt;OS&gt;&quot; }</td>
</tr>
<tr>
<td>Nodes with a specific report status (example: last run failed)</td>
<td>reports[certname] { latest_report_status = &quot;failed&quot; }</td>
</tr>
<tr>
<td>Nodes with a specific class (example: Apache)</td>
<td>resources[certname] { type = &quot;Class&quot; and title = &quot;Apache&quot; }</td>
</tr>
<tr>
<td>Nodes assigned to a specific environment (example: production)</td>
<td>nodes[certname] { catalog_environment = &quot;production&quot; }</td>
</tr>
<tr>
<td>Nodes with a specific version of a resource type (example: OpenSSL is v1.1.0e)</td>
<td>resources[certname] { type = &quot;Package&quot; and title=&quot;openssl&quot; and parameters.ensure = &quot;1.0.1e-51.el7_2.7&quot; }</td>
</tr>
<tr>
<td>Nodes with a specific resource and operating system (example: httpd and CentOS)</td>
<td>inventory[certname] { facts.operatingsystem = &quot;CentOS&quot; and resources { type = &quot;Service&quot; and title = &quot;httpd&quot; } }</td>
</tr>
</tbody>
</table>

10. Click **Submit query** and click **Refresh** to update the node results.
11. If you change or edit the query after it runs, click Submit query again.

12. Optional: To convert the PQL query target results to a node list, for use as a node list target, click Convert query to static node list.

   Note: If you select this option, the job target becomes a node list. You can add or remove nodes from the node list before running the job, but you cannot edit the query.

13. Click Run task or Schedule job.

   Your task run appears on the Tasks page. Click the ID number to view the results and output.

   Tip: Filter run results by task name to find specific task runs.

   Important: When you run this job, the PQL query runs again, and the job might run on a different set of nodes than what is currently displayed. If you want the job to run only on the list as displayed, convert the query to a static node list before you run the job.

Add custom PQL queries to the console
Add your own PQL queries to the console and quickly access them when running jobs.

1. On your Master, as root, copy the custom_pql_queries.json.example file and remove the example suffix.

   cp /etc/puppetlabs/console-services/custom_pql_queries.json.example /etc/puppetlabs/console-services/custom_pql_queries.json

2. Edit the file contents to include your own PQL queries or remove any existing queries.
3. Refresh the console UI in your browser.

   You can now see your custom queries in the PQL drop down options when running jobs.

Run a task on a node group
Similar to running a task on a list of nodes that you create in the console, you can run a task on a node group.

Before you begin
Install the tasks you want to use.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

Note: If you do not have permissions to view a node group, or the node group doesn't have any matching nodes, that node group won't be listed as an option for viewing. In addition, a node group does not appear if no rules have been specified for it.

1. In the console, in the Orchestration section, click Tasks.
2. Click Run a task in the upper right corner of the Tasks page.
3. In the Code environment field, select the environment where you installed the module containing the task you want to run. This defaults to production.
4. In the Task field, select a task to run, for example service.

   Note: If the tasks you expect are not available, you either have no tasks installed, or you don't have the correct permissions to run them.
5. Optional: In the Job description field, provide a description. The text you enter here appears on the job list and job details pages.
6. Under **Task parameters**, add optional parameters and enter values for the optional and required parameters on the list.

   **Important:** You must click **Add parameter** for each optional parameter-value pair you add to the task.

   To view information about required and optional parameters for the task, select **view task metadata** below the **Task** field.

   Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (" "). Structured values, like an array, must be valid JSON.

   Tasks with default values run using the default value unless another value is specified.

   **Note:** The parameters you supplied the first time you ran a task will be used for subsequent tasks run when using the **Run again** feature on the **Task details** page.

7. Optional: Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.

   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

8. From the list of target types, select **Node group**.

9. In the **Choose a node group** box, type or select a node group, and click **Select**.

10. Click **Run task** or **Schedule job**.

    Your task run appears on the **Tasks** page. Click the **ID** number to view the results and output.

    **Tip:** Filter run results by task name to find specific task runs.

**Stop a task in progress**

You can stop a task in progress if, for example, you realize you need to adjust your PQL query or edit the parameters the task run needs.

When you stop a task run, runs that are underway still finish but no new tasks start on the node until you run again.

To stop a task

- In the console, on the **Tasks** page, find the task run you want to stop and click **Stop job**.
- On the command line, press **CTRL + C**.

**Running tasks from the command line**

Use the `puppet task run` command to run tasks on agent nodes.

**Before you begin**

The first time you run a command, you need to authenticate. See the orchestrator installation instructions for information about setting RBAC permissions and token authorization.

If you're running this command from a managed or non-managed Windows workstation, you must specify the full path to the command. For example, `c:\Program Files\Puppet Labs\Client\bin\puppet-task run`.

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

**Tip:** You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.

Make sure you have permissions to run tasks and PQL queries.

Make sure you have permissions to run jobs and PQL queries.

© 2020 Puppet, Inc.
Use the puppet task tool and the relevant module to make changes arbitrarily, rather than through a Puppet configuration change. For example, to inspect a package or quickly stop a particular service.

You can run tasks on a single node, on nodes identified in a static list, on nodes retrieved by a PQL query, or on nodes in a node group.

Use the orchestrator command pumpet task to trigger task runs.

**Run a task on a PQL query**
Create a PQL query to run tasks on nodes that meet specific conditions.

**Before you begin**
Install the tasks you want to use.

Make sure you have access to the nodes you want to target.

Make sure you have permissions to run tasks and PQL queries.

Log into your master or client tools workstation and run one of the following commands:

- To specify the query on the command line: `puppet task run <TASK NAME> <PARAMETER>=<VALUE>, <PARAMETER>=<VALUE> --query 'QUERY' OPTIONS`
- To pass the query in a text file: `puppet task run <TASK NAME> <PARAMETER>=<VALUE>, <PARAMETER>=<VALUE> --query @/path/to/file.txt`

For example, to run the service task with two required parameters, on nodes with "web" in their certname:

```
puppet task run service action=status service=nginx --query 'nodes { certname ~ "web" }'
```

**Tip:** Use `puppet task show <TASK NAME>` to see a list of available parameters for a task. Not all tasks require parameters.

Refer to the puppet task command options to see how to pass parameters with the --params flag.

The following table shows some example targets and the associated PQL queries you could run with the orchestrator.

Be sure to wrap the entire query in single quotes and use double quotes inside the query.

<table>
<thead>
<tr>
<th>Target</th>
<th>PQL query</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single node by certname</td>
<td>--query 'nodes { certname = &quot;mynode&quot; }'</td>
</tr>
<tr>
<td>All nodes with &quot;web&quot; in certname</td>
<td>--query 'nodes { certname ~ &quot;web&quot; }'</td>
</tr>
<tr>
<td>All CentOS nodes</td>
<td>--query 'inventory { facts.os.name = &quot;CentOS&quot; }'</td>
</tr>
<tr>
<td>All CentOS nodes with httpd managed</td>
<td>--query 'inventory { facts.operatingsystem = &quot;CentOS&quot; and resources { type = &quot;Service&quot; and title = &quot;httpd&quot; } }'</td>
</tr>
<tr>
<td>All nodes with failed reports</td>
<td>--query 'reports { latest_report? = true and status = &quot;failed&quot; }'</td>
</tr>
<tr>
<td>All nodes matching the environment for the last received catalog</td>
<td>--query 'nodes { catalog_environment = &quot;production&quot; }'</td>
</tr>
</tbody>
</table>

**Tip:** You can use --q in place of --query.
Run a task on a list of nodes or a single node
Use a node list target when you need to run a job on a set of nodes that doesn't easily resolve to a PQL query. Use a single node or a comma-separated list of nodes.

Before you begin
Install the tasks you want to use.
Make sure you have access to the nodes you want to target.
Make sure you have permissions to run tasks and PQL queries.

Log into your master or client tools workstation and run one of the following commands:

• To run a task job on a single node:
  
  puppet task run <TASK NAME> <PARAMETER>=<VALUE>,
  <PARAMETER>=<VALUE> --nodes <NODE NAME> <OPTIONS>

• To run a task job on a list of nodes, use a comma-separated list of node names:
  puppet task run <TASK NAME> <PARAMETER>=<VALUE>, <PARAMETER>=<VALUE> --nodes <NODE NAME>,<NODE NAME>,<NODE NAME>,<NODE NAME> <OPTIONS>

  Note: Do not add spaces in the list of nodes.

• To run a task job on a node list from a text file:
  puppet task run <TASK NAME> <PARAMETER>=<VALUE>, <PARAMETER>=<VALUE> --nodes @/path/to/file.txt

  Note: In the text file, put each node on a separate line.

For example, to run the service task with two required parameters, on three specific hosts:

  puppet task run service action=status service=nginx --nodes host1,host2,host3

Tip: Use puppet task show <TASK NAME> to see a list of available parameters for a task. Not all tasks require parameters.

Refer to the puppet task command options to see how to pass parameters with the --params flag.

Run a task on a node group
Similar to running a task on a list of nodes, you can run a task on a node group.

Before you begin
Install the tasks you want to use.
Make sure you have access to the nodes you want to target.

1. Log into your master or client tools workstation.
2. Run the command:
  puppet task run <TASK NAME> --node-group <node-group-id>

  Tip: Use the /v1/groups endpoint to retrieve a list node groups and their IDs.

Related information
GET /v1/groups on page 361
Use the `/v1/groups` endpoint to retrieve a list of all node groups in the node classifier.

**puppet task run command options**

The following are common options you can use with the `task` action. For a complete list of global options run `puppet task --help`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--noop</code></td>
<td>Flag, default false</td>
<td>Run a task to simulate changes without actually enforcing the changes.</td>
</tr>
<tr>
<td><code>--params</code></td>
<td>String</td>
<td>Specify a JSON object that includes the parameters, or specify the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>path to a JSON file containing the parameters, prefaced with</td>
</tr>
<tr>
<td></td>
<td></td>
<td>@, for example, @/path/to/file.json. Do not use this flag if specifying</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parameter-value pairs inline; see more information below.</td>
</tr>
<tr>
<td><code>--environment,-e</code></td>
<td>Environment name</td>
<td>Use tasks installed in the specified environment.</td>
</tr>
<tr>
<td><code>--description</code></td>
<td>Flag, defaults to empty</td>
<td>Provide a description for the job, to be shown on the job list and job</td>
</tr>
<tr>
<td></td>
<td></td>
<td>details pages, and returned with the <code>puppet job show</code> command.</td>
</tr>
</tbody>
</table>

You can pass parameters into the task one of two ways:

- **Inline**, using the `<PARAMETER>=<VALUE>` syntax:

  ```
puppet task run <TASK NAME> <PARAMETER>=<VALUE>, <PARAMETER>=<VALUE> --nodes <LIST OF NODES>
puppet task run my_task action=status service=my_service timeout=8 --nodes host1,host2,host3
  ```

- **With the `--params` option**, as a JSON object or reference to a JSON file:

  ```
puppet task run <TASK NAME> --params '{ "action":"status", "service":"my_service", "timeout":8 }' --nodes host1,host2,host3
puppet task run my_task --params @/path/to/file.json --nodes host1,host2,host3
  ```

You can’t combine these two ways of passing in parameters; choose either inline or `--params`. If you use the inline way, parameter types other than string, integer, double, and Boolean will be interpreted as strings. Use the `--params` method if you want them read as their original type.

**Reviewing task job output**

The output the orchestrator returns depends on the type of task you run. Output is either standard output (STDOUT) or structured output. At minimum, the orchestrator prints a new job ID and the number of nodes in the task.

The following example shows a task to check the status of the Puppet service running on a list of nodes derived from a PQL query.

```bash
/example@orch-master ~]$ puppet task run service service=puppet action=status -q 'nodes {certname ~ "br"}' --environment=production
Starting job ...
New job ID: 2029
```
Nodes: 8

Finished on node bronze-5
  status : running
  enabled : true
Finished on node bronze-10
  status : running
  enabled : true

Job completed. 8/8 nodes succeeded.
Duration: 1 sec

Tip: To view the status of all running, completed, and failed jobs run the puppet job show command, or view them from the Job details page in the console.

Inspect tasks
View the tasks that you have installed and have permission to run, as well as the documentation for those tasks.

Before you begin
The first time you run a command, you need to authenticate. See the orchestrator installation instructions for information about setting RBAC permissions and token authorization.

If you're running this command from a managed or non-managed Windows workstation, you must specify the full path to the command. For example, c:\Program Files\Puppet Labs\Client\bin\puppet-task run.

Install the tasks you want to use.

Make sure you have permission to run the tasks on all nodes.

Make sure you have permission to run the tasks.

Make sure you have access to the nodes you want to target.

Tip: You can add network devices to a node list when you have installed modules for device transports in your production environment. You can find such modules in Puppet Forge.
Make sure you have permissions to run tasks and PQL queries.

Install the tasks you want to use.

Log into your master or client tools workstation and run one of the following commands:

- To check the documentation for a specific task: `puppet task show <TASK>`. The command returns the following:
  - The command format for running the task
  - Any parameters available to use with the task
- To view a list of your permitted tasks: `puppet task show`
- To view a list of all installed tasks pass the `--all` flag: `puppet task show --all`

**Stop a task in progress**
You can stop a task in progress if, for example, you realize you need to adjust your PQL query or edit the parameters the task run needs.

When you stop a task run, runs that are underway still finish but no new tasks start on the node until you run again.

To stop a task

- In the console, on the **Tasks** page, find the task run you want to stop and click **Stop job**.
- On the command line, press **CTRL + C**.

**Scheduling tasks**
When you run tasks in the console, you have the option to schedule a recurring task, schedule a task for later, or delete a scheduled task.

**Schedule a task**
Schedule a task to run at a particular date and time or set a recurring task that runs on a regular schedule.

**Before you begin**
Install the tasks you want to use.

Make sure you have access to the nodes you want to target.

1. In the console, in the **Orchestration** section, click **Tasks**.
2. Optional: In the **Job description** field, provide a description. The text you enter here appears on the job list and job details pages.
3. In the **Task** field, select a task to run, for example **service**.
   - **Note:** If the tasks you expect are not available, you either have no tasks installed, or you don't have the correct permissions to run them.
4. Under **Task parameters**, add optional parameters and enter values for the optional and required parameters on the list.
   - **Important:** You must click **Add parameter** for each optional parameter-value pair you add to the task.
   - To view information about required and optional parameters for the task, select **view task metadata** below the **Task** field.
   - Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (" "). Structured values, like an array, must be valid JSON.
   - Tasks with default values run using the default value unless another value is specified.
   - **Note:** The parameters you supplied the first time you ran a task will be used for subsequent tasks run when using the **Run again** feature on the **Task details** page.
5. Under **Schedule**, select **Later** and choose a start date, time, time zone, and frequency for the job to run.  
   
   **Tip:** Based on the configuration of your console, the default time zone is either UTC, Coordinated Universal Time, or the local time, UTC offset, of your browser.

6. Optional: To repeat the job on a regular schedule, change the run frequency from **Once** to **Hourly, Daily**, or **Weekly**.

   **Note:** If a recurring job runs longer than the selected frequency, the following job waits to start until the next available time interval.

7. From the list of target types, select the category of nodes you want to target.

   - **Node list** Add individual nodes by name.
   - **PQL Query** Use the Puppet query language to retrieve a list of nodes.
   - **Node group** Select an existing node group.

8. Click **Schedule job**.

   Your task appears on the **Scheduled task** tab of the **Jobs** page.

**Related information**

**Console and console-services parameters** on page 101

Use these parameters to customize the behavior of the console and console-services. Parameters that begin with `puppet_enterprise::profile` can be modified from the console itself. See the configuration methods documents for more information on how to change parameters in the console or Hiera.

**Delete a scheduled job** on page 447

Delete a job that is scheduled to run at a later time.

**Delete a scheduled task**

Delete a task that is scheduled to run later.

**Tip:** You must have the appropriate role-based permissions to delete another user's scheduled task.

1. In the console, on the **Tasks** page, select the **Scheduled Tasks** tab.
2. Find the task you want to delete and select **Remove**.

**Running plans in PE**

Use the orchestrator to set up jobs in the console or on the command line and run plans across systems in your infrastructure.

- **Running plans from the console** on page 472
  Run ad hoc plans from the console.
- **Running plans from the command line** on page 473
  Run a plan using the `puppet plan run` command.
- **Plan caveats and limitations** on page 474
  Some plan language and features are not available in PE or have some caveats.
- **Inspecting plans** on page 477
  View the plans you have installed and which ones you have permissions to run, as well as details about individual plans.

**Running plans from the console**

Run ad hoc plans from the console.

**Before you begin**

Install the plans you want to use.

Make sure you have permission to run the plans.
When you set up a job to run a plan from the console, the orchestrator creates a job ID to track the job, shows the nodes included in the job, and runs the plan on those nodes in the appropriate order. Puppet compiles a new catalog for each node included in the job.

**Note:** Running a plan does not update your Puppet configuration. If you run a plan that changes the state of a resource that Puppet is managing (such as upgrading a service or package), a subsequent Puppet run changes the state of that resource back to what is defined in your Puppet configuration.

1. In the console, in the **Orchestration** section, select **Plans**.
2. Click **Run a plan** in the upper right corner.
3. Under **Code environment**, select the environment where you installed the module containing the plan you want to run. For example, **production**.
4. Optional: Under **Job description**, provide a description. The text you enter here appears on the **Plans** page.
5. Under **Plan**, select the plan you want to run.
6. Under **Plan parameters**, add optional parameters, then enter values for the optional and required parameters on the list. Click **Add parameter** for each optional parameter-value pair you add to the plan.

To view information about required and optional parameters for the plan, select **view plan metadata** below the **Plan** field.

Express values as strings, arrays, objects, integers, or booleans (true or false). You must express empty strings as two double quotes with no space (" "). Structured values, like an array, must be valid JSON.

Plans with default values run using the default value unless another value is specified.

7. Select **Run job**.

Your plan status and output will appear on the **Plans** page.

**Running plans from the command line**

Run a plan using the **puppet plan run** command.

On the command line, run the command `puppet plan run` with the following information included:

- The full name of the plan, formatted as `<MODULE>::<PLAN>`.
- Any plan parameters.

**Note:** To find out what parameters can be included in a plan, view the plan metadata by running the command `puppet plan show <PLAN NAME>` on the command line. For more information, see Inspecting plans on page 477

- Credentials, if required, formatted with the **--user** and **--password** flags.

For example, if a plan defined in `mymodule/plans/myplan.pp` accepts a `load_balancer` parameter, run:

```
puppet plan run mymodule::myplan load_balancer=lb.myorg.com
```

You can pass a comma-separated list of node names, wildcard patterns, or group names to a plan parameter that is passed to a run function or that the plan resolves using `get_targets`.

**Plan command options**

The following are common options you can use with the **plan** action. For a complete list of global options run `puppet plan --help`.

- **--params** - A string value used to specify a JSON object that includes the parameters, or specify the path to a JSON file containing the parameters, prefaced with @. For example, @/path/to/file.json. Do not use this flag if specifying parameter-value pairs inline.
- **--environment or -e** - The name of the environment where plans are installed.
- **--description** - A flag used to provide a description for the job to be shown on the job list and job details pages and returned with the **puppet job show** command. It defaults to empty.

You can pass parameters into the plan one of two ways:

- Inline, using the `<PARAMETER>=<VALUE>` syntax

© 2020 Puppet, Inc.
With the --params option, as a JSON object or reference to a JSON file.

For example, review this plan:

```ruby
plan example::test_params(Targetspec $nodes, String $command){
  run_command($command, $nodes)
}
```

You can pass parameters using either option below:

1. `puppet plan run example::test_params nodes=my-node.company.com command=whoami`
2. `puppet plan run example::test_params --params '{"nodes":"my-node.company.com", "command":"whoami"}'`

You can't combine these two ways of passing in parameters. Choose either inline or --params.

If you use the inline way, parameter types other than string, integer, double, and Boolean will be interpreted as strings. Use the --params method if you want them read as their original type.

**Plan caveats and limitations**

Some plan language and features are not available in PE or have some caveats.

**Bolt modules are not included**

The following modules that come pre-installed with open source Bolt are not available by default in PE:

- `aggregate`
- `canary`
- `puppetdb_fact`
- `ruby_task_helper`
- `python_task_helper`
- `facts`
  - The PE equivalent of facts is factor_task
- `puppet_agent`
  - The PE equivalent of puppet_agent is pe_bootstrap

**Plan language functions**

The following Bolt plan functions will not work in PE and using them will cause a plan to fail:

- `file::read`
- `file::write`
- `file::readable`
- `file::exists`
- `set_feature`
- `add_to_group`
- `set_config`

**Apply blocks**

The apply feature, including apply_prep, only works only for targets using the PXP agent and the PCP transport. It will fail on targets connected via SSH or WinRM.
**Target groups**

Support for target groups is unavailable in PE. Using `add_to_group` will cause a plan to fail and referencing a group name in `get_targets` will not return any nodes. When using `get_targets` you **must** reference either node certnames or supply a PuppetDB query.

Here is an example of a plan using `get_targets` with node certnames:

```perl
plan example::get_targets_example () {
    $nodes = get_targets(['node1.example.com', 'node2.example.com'])
    run_command('whoami', $nodes)
}
```

**Target features**

Support for target features is unavailable in PE. Using `set_feature` will cause a plan to fail and referencing a target object’s features list will always return an empty array.

Here is an example of a plan that would return an empty features list:

```perl
plan example::empty_features_example (TargetSpec $node) {
    return get_target($node).features()
}
```

**Target configuration**

While you can set up node transport configuration through the PE inventory for nodes to use SSH or WinRM, plans in PE do not support setting or changing the configuration settings for targets from within a plan. Using the `set_config` function in a plan will cause a plan to fail and referencing a target object’s configuration hash will always return an empty hash.

The use of URIs in a target name to override the transport is also not supported. All references to targets (i.e. when using `get_targets`) must be either PuppetDB queries or valid certnames that are already in the PE inventory.

Here is an example of a plan that uses `get_targets` correctly:

```perl
plan example::get_targets_example () {
    ## NOTE! If you used ssh://node1.example.com as the first entry, this plan
    ## would fail!
    $nodes = get_targets(['node1.example.com', 'node2.example.com'])
    run_command('whoami', $nodes)
}
```

**_run_as options in plan functions**

Plans in PE does not support the `_run_as` parameter for changing the user that accesses hosts or executes actions. If this parameter is supplied to any plan function, the plan will execute but the user will not change.

For example, the following plan will succeed, but will not run as `other_user`:

```perl
plan example::run_as_example (TargetSpec $nodes) {
    run_command('whoami', $nodes, _run_as => 'other_user')
}
```

**The localhost target**

The special target `localhost` is not available for plans in PE. Using `localhost` anywhere in a plan will result in a plan failure. If you need to run a plan on the PE master host, use the master's certname to reference it.
For example, you can use the following plan for PE master host `my-pe-master.company.com`:

```ruby
plan example::referencing_the_master(){
  # Note that if you tried to use `localhost` instead of `my-pe-master` this
  # plan would fail!
  run_command('whoami', 'my-pe-master.company.com')
}
```

### Standard Puppet log functions

Puppet’s built-in logging functions, like `notice` and `warn`, will not log anywhere. Plans with those functions will still work, but the logging messages will not appear.

If you need to use a logging function in your plan, the `out::message()` plan function will write an event to the orchestrator's event stream.

For example, the following will log the message correctly to the event stream:

```ruby
plan example::logging(){
  out::message("This will output to the orchestrator event stream")
}
```

This will not log any messages:

```ruby
plan example::bad_logging(){
  # neither of the following will output any messages anywhere
  notice("this will go nowhere!")
  warn("this will also go nowhere!")
}
```

### Script and file sources

When using `run_script` or `download_file`, the source location for the files **must** be from a module that uses a modulename/filename selector for a file or directory in `$MODULEROOT/files`. PE does not support file sources that reference absolute paths.

Here is an example of a module structure and a plan that correctly uses the modulename/filename selector:

```erb
example/
  ### files
  ###my_script.sh
  ### plans
  ###run_script_example.pp

plan example::run_script_example (TargetSpec $nodes) {
  run_script('example/my_script.sh', $nodes)
}
```

### Code deployment for plans

For plans in PE to work, you must have code manager enabled to deploy code to your master.

Masters will now deploy a second codedir for plans to load code from. The second code location on masters have some effects on standard module functionality:

- Installation modules using the `puppet module install` command will not work for plans because the puppet module tool will not install to the secondary location for plans. The `puppet module install` command will still work for normal Puppet code executed and compiled from Puppet Server.
- A `$modulepath` configuration that uses fully qualified paths might not work for plans if they reference the standard `/etc/puppetlabs/code` location. We recommend using relative paths in `$modulepath`.  

© 2020 Puppet, Inc.
**Inspecting plans**

View the plans you have installed and which ones you have permissions to run, as well as details about individual plans.

Log into your master or client tools workstation and run one of the following commands to see information about your plan inventory:

- `puppet plan show` - View a list of your permitted plans.
- `puppet plan show --all` - View a list of all installed plans.

Use the command `puppet plan show <PLAN NAME>` to view plan metadata. The output includes the command format and parameters available to use for an individual plan.

For example, this plan allows a `$nodes` parameter and a `$version` parameter, specified as data types `TargetSpec` and `Integer`.

```ruby
plan infra::upgrade_apache (  
    TargetSpec $nodes,  
    Integer $version,  
) {  
    run_task('package', $nodes, name => 'apache', action => 'upgrade', version => $version)  
}
```

To view plan metadata in the console, choose which plan you want to run in the **Plan** field and click on the **View plan metadata** link.

**Writing tasks**

Bolt tasks are similar to scripts, but they are kept in modules and can have metadata. This allows you to reuse and share them.

You can write tasks in any programming language the target nodes run, such as Bash, PowerShell, or Python. A task can even be a compiled binary that runs on the target. Place your task in the `.tasks` directory of a module and add a metadata file to describe parameters and configure task behavior.

For a task to run on remote *nix systems, it must include a shebang (`#!/`) line at the top of the file to specify the interpreter.

For example, the Puppet `mysql::sql` task is written in Ruby and provides the path to the Ruby interpreter. This example also accepts several parameters as JSON on stdin and returns an error.

```ruby
#!/opt/puppetlabs/puppet/bin/ruby
require 'json'
require 'open3'
require 'puppet'
def get(sql, database, user, password)
    cmd = ['mysql', '-e', "#{sql}" ]
    cmd << "--database=#{database}" unless database.nil?
    cmd << "--user=#{user}" unless user.nil?
    cmd << "--password=#{password}" unless password.nil?
    stdout, stderr, status = Open3.capture3(*cmd) # rubocop:disable Lint/UselessAssignment
    raise Puppet::Error, _("stderr: ' %{stderr}' % { stderr: stderr }") if status != 0
    { status: stdout.strip }
end

params = JSON.parse(STDIN.read)
database = params['database']
```
user = params['user']
password = params['password']
sql = params['sql']

begin
    result = get(sql, database, user, password)
    puts result.to_json
    exit 0
rescue Puppet::Error => e
    puts({ status: 'failure', error: e.message }.to_json)
    exit 1
end

This table shows which version of the Puppet task specification is compatible with each version of PE.

### Secure coding practices for tasks

Use secure coding practices when you write tasks and help protect your system.

**Note:** The information in this topic covers basic coding practices for writing secure tasks. It is not an exhaustive list.

One of the methods attackers use to gain access to your systems is remote code execution, where by running an allowed script they gain access to other parts of the system and can make arbitrary changes. Because Bolt executes scripts across your infrastructure, it is important to be aware of certain vulnerabilities, and to code tasks in a way that guards against remote code execution.

Adding task metadata that validates input is one way to reduce vulnerability. When you require an enumerated (enum) or other non-string types, you prevent improper data from being entered. An arbitrary string parameter does not have this assurance.

For example, if your task has a parameter that selects from several operational modes that are passed to a shell command, instead of

```ruby
String $mode = 'file'
```

use

```ruby
Enum[file,directory,link,socket] $mode = file
```

If your task has a parameter that identifies a file on disk, ensure that a user can't specify a relative path that takes them into areas where they shouldn't be. Reject file names that have slashes.

Instead of

```ruby
String $path
```

use

```ruby
Pattern[/\A[^/\\]*\z/] $path
```

In addition to these task restrictions, different scripting languages each have their own ways to validate user input.

#### PowerShell

In PowerShell, code injection exploits calls that specifically evaluate code. Do not call `Invoke-Expression` or `Add-Type` with user input. These commands evaluate strings as C# code.
Reading sensitive files or overwriting critical files can be less obvious. If you plan to allow users to specify a file name or path, use Resolve-Path to verify that the path doesn't go outside the locations you expect the task to access. Use Split-Path -Parent $path to check that the resolved path has the desired path as a parent. For more information, see PowerShell Scripting and Powershell's Security Guiding Principles.

**Bash**

In Bash and other command shells, shell command injection takes advantage of poor shell implementations. Put quotations marks around arguments to prevent the vulnerable shells from evaluating them. Because the eval command evaluates all arguments with string substitution, avoid using it with user input; however you can use eval with sufficient quoting to prevent substituted variables from being executed.

Instead of

```
  eval "echo $input"
```

use

```
  eval "echo '$input'"
```

These are operating system-specific tools to validate file paths: realpath or readlink -f.

**Python**

In Python malicious code can be introduced through commands like eval, exec, os.system, os.popen, and subprocess.call with shell=True. Use subprocess.call with shell=False when you include user input in a command or escape variables.

Instead of

```
  os.system('echo '+input)
```

use

```
  subprocess.check_output(['echo', input])
```

Resolve file paths with os.realpath and confirm them to be within another path by looping over os.path.dirname and comparing to the desired path.

For more information on the vulnerabilities of Python or how to escape variables, see Kevin London's blog post on Dangerous Python Functions.

**Ruby**

In Ruby, command injection is introduced through commands like eval, exec, system, backtick (`) or %x() execution, or the Open3 module. You can safely call these functions with user input by passing the input as additional arguments instead of a single string.

Instead of

```
  system("echo #{flag1} #{flag2}"
```

use

```
  system('echo', flag1, flag2)
```

Resolve file paths with Pathname#realpath, and confirm them to be within another path by looping over Pathname#parent and comparing to the desired path.
For more information on securely passing user input, see the blog post Stop using backtick to run shell command in Ruby.

**Naming tasks**

Task names are named based on the filename of the task, the name of the module, and the path to the task within the module.

You can write tasks in any language that runs on the target nodes. Give task files the extension for the language they are written in (such as .rb for Ruby), and place them in the top level of your module's ./tasks directory.

Task names are composed of one or two name segments, indicating:

- The name of the module where the task is located.
- The name of the task file, without the extension.

For example, the puppetlabs-mysql module has the sql task in ./mysql/tasks/sql.rb, so the task name is mysql::sql. This name is how you refer to the task when you run tasks.

The task filename init is special: the task it defines is referenced using the module name only. For example, in the puppetlabs-service module, the task defined in init.rb is the service task.

Each task or plan name segment must begin with a lowercase letter and:

- Must start with a lowercase letter.
- Can include digits.
- Can include underscores.
- Namespace segments must match the following regular expression \A[a-z][a-z0-9_]*\Z
- The file extension must not use the reserved extensions .md or .json.

**Single-platform tasks**

A task can consist of a single executable with or without a corresponding metadata file. For instance, ./mysql/tasks/sql.rb and ./mysql/tasks/sql.json. In this case, no other ./mysql/tasks/sql.* files can exist.

**Cross-platform tasks**

A task can have multiple implementations, with metadata that explains when to use each one. A primary use case for this is to support different implementations for different target platforms, referred to as *cross-platform tasks*.

A task can also have multiple implementations, with metadata that explains when to use each one. A primary use case for this is to support different implementations for different target platforms, referred to as *cross-platform tasks*. For instance, consider a module with the following files:

- tasks
  - sql_linux.sh
  - sql_linux.json
  - sql_windows.ps1
  - sql_windows.json
  - sql.json

This task has two executables (sql_linux.sh and sql_windows.ps1), each with an implementation metadata file and a task metadata file. The executables have distinct names and are compatible with older task runners such as Puppet Enterprise 2018.1 and earlier. Each implementation has its own metadata which documents how to use the implementation directly or marks it as private to hide it from UI lists.

An implementation metadata example:

```json
{
    "name": "SQL Linux",
    "description": "A task to perform sql operations on linux targets",
}```
The task metadata file contains an implementations section:

```json
{
  "implementations": [
    {
      "name": "sql_linux.sh", "requirements": ["shell"]
    },
    {
      "name": "sql_windows.ps1", "requirements": ["powershell"]
    }
  ]
}
```

Each implementations has a name and a list of requirements. The requirements are the set of features which must be available on the target in order for that implementation to be used. In this case, the `sql_linux.sh` implementation requires the `shell` feature, and the `sql_windows.ps1` implementations requires the PowerShell feature.

The set of features available on the target is determined by the task runner. You can specify additional features for a target via `set_feature` or by adding `features` in the inventory. The task runner chooses the first implementation whose requirements are satisfied.

The following features are defined by default:
- **puppet-agent**: Present if the target has the Puppet agent package installed. This feature is automatically added to hosts with the name `localhost`.
- **shell**: Present if the target has a posix shell.
- **powershell**: Present if the target has PowerShell.

**Sharing executables**

Multiple task implementations can refer to the same executable file.

Executables can access the `_task` metaparameter, which contains the task name. For example, the following creates the tasks `service::stop` and `service::start`, which live in the executable but appear as two separate tasks.

```ruby
#!/usr/bin/env ruby
require 'json'
params = JSON.parse(STDIN.read)
action = params['action'] || params['_task']
if ['start', 'stop'].include?(action)
  `systemctl #{params['_task']} #{params['service']}`
end
```

```json
{
  "description": "Start a service",
  "parameters": {
    "service": {
      "type": "String",
      "description": "The service to start"
    }
  },
  "implementations": [
    {
      "name": "init.rb"
    }
  ]
}
```
myservice/tasks/stop.json

```
{
    "description": "Stop a service",
    "parameters": {
        "service": {
            "type": "String",
            "description": "The service to stop"
        }
    },
    "implementations": [
        {"name": "init.rb"}
    ]
}
```

### Sharing task code

Multiple tasks can share common files between them. Tasks can additionally pull library code from other modules.

To create a task that includes additional files pulled from modules, include the files property in your metadata as an array of paths. A path consists of:

- the module name
- one of the following directories within the module:
  - files — Most helper files. This prevents the file from being treated as a task or added to the Puppet Ruby loadpath.
  - tasks — Helper files that can be called as tasks on their own.
  - lib — Ruby code that might be reused by types, providers, or Puppet functions.
- the remaining path to a file or directory; directories must include a trailing slash `/`

All path separators must be forward slashes. An example would be `stdlib/lib/puppet/`.

The `files` property can be included both as a top-level metadata property, and as a property of an implementation, for example:

```
{
    "implementations": [
        {"name": "sql_linux.sh", "requirements": ["shell"], "files": ["mymodule/files/lib.sh"]},
        {"name": "sql_windows.ps1", "requirements": ["powershell"], "files": ["mymodule/files/lib.ps1"]}
    ],
    "files": ["emoji/files/emojis/"]
}
```

When a task includes the `files` property, all files listed in the top-level property and in the specific implementation chosen for a target are copied to a temporary directory on that target. The directory structure of the specified files is preserved such that paths specified with the `files` metadata option are available to tasks prefixed with `_installdir`. The task executable itself is located in its module location under the `_installdir` as well, so other files can be found at `../../mymodule/files/` relative to the task executable's location.

For example, you can create a task and metadata in a module at `~/.puppetlabs/bolt/site-modules/mymodule/tasks/task.{json,rb}`.

### Metadata

```
{
    "files": ["multi_task/files/rb_helper.rb"]
}
```
File resource

multi_task/files/rb_helper.rb

def useful_ruby
    { helper: "ruby" }
end

Task

#!/usr/bin/env ruby
require 'json'

params = JSON.parse(STDIN.read)
require_relative File.join(params['_installdir'], 'multi_task', 'files', 'rb_helper.rb')
# Alternatively use relative path
# require_relative File.join(__dir__, '..', '..', 'multi_task', 'files', 'rb_helper.rb')
puts useful_ruby.to_json

Output

Started on localhost...
Finished on localhost:
  { "helper": "ruby" }
Successful on 1 node: localhost
Ran on 1 node in 0.12 seconds

Task helpers

To help with writing tasks, Bolt includes python_task_helper and ruby_task_helper. It also makes a useful demonstration of including code from another module.

Python example

Create task and metadata in a module at ~/.puppetlabs/bolt/site-modules/mymodule/tasks/task.{json,py}.

Metadata

{
    "files": ["python_task_helper/files/task_helper.py"],
    "input_method": "stdin"
}

Task

#!/usr/bin/env python
import os, sys
sys.path.append(os.path.join(os.path.dirname(__file__), '..', '..', 'python_task_helper', 'files'))
from task_helper import TaskHelper

class MyTask(TaskHelper):
    def task(self, args):
        return {'greeting': 'Hi, my name is '+'+args['name']}

© 2020 Puppet, Inc.
if __name__ == '__main__':
    MyTask().run()

Output

$ bolt task run mymodule::task -n localhost name='Julia'
Started on localhost...
Finished on localhost:
    {  
        "greeting": "Hi, my name is Julia"  
    }
Successful on 1 node: localhost
Ran on 1 node in 0.12 seconds

Ruby example

Create task and metadata in a new module at ~/.puppetlabs/bolt/site-modules/mymodule/tasks/mymodule::mytask.(json,rb).

Metadata

Task

#!/usr/bin/env ruby
require_relative '../../ruby_task_helper/files/task_helper.rb'
class MyTask < TaskHelper
    def task(name: nil, **kwargs)
        { greeting: "Hi, my name is #{name}" }
    end
end
MyTask.run if __FILE__ == $0

Output

$ bolt task run mymodule::mytask -n localhost name="Robert''); DROP TABLE Students;--"  
Started on localhost...
Finished on localhost:
    {  
        "greeting": "Hi, my name is Robert'"); DROP TABLE Students;--"  
    }
Successful on 1 node: localhost
Ran on 1 node in 0.12 seconds

Writing remote tasks

Some targets are hard or impossible to execute tasks on directly. In these cases, you can write a task that runs on a proxy target and remotely interacts with the real target.

For example, a network device might have a limited shell environment or a cloud service might be driven only by HTTP APIs. By writing a remote task, Bolt allows you to specify connection information for remote targets in their inventory file and injects them into the _target metaparam.
This example shows how to write a task that posts messages to Slack and reads connection information from inventory.yaml:

```
#!/usr/bin/env ruby
# modules/slack/tasks/message.rb

require 'json'
require 'net/http'

params = JSON.parse(STDIN.read)
# the slack API token is passed in from inventory
token = params['_target']['token']

uri = URI('https://slack.com/api/chat.postMessage')
http = Net::HTTP.new(uri.host, uri.port)
http.use_ssl = true

req = Net::HTTP::Post.new(uri, 'Content-type' => 'application/json')
req['Authorization'] = "Bearer #{params['_target']['token']}"
req.body = { channel: params['channel'], text: params['message'] }.to_json

resp = http.request(req)
puts resp.body
```

To prevent accidentally running a normal task on a remote target and breaking its configuration, Bolt won’t run a task on a remote target unless its metadata defines it as remote:

```
{
  "remote": true
}
```

Add Slack as a remote target in your inventory file:

```
---
nodes:
  - name: my_slack
    config:
      transport: remote
      remote:
        token: <SLACK_API_TOKEN>
```

Finally, make `my_slack` a target that can run the `slack::message`:

```
bolt task run slack::message --nodes my_slack message="hello" channel=<slack channel id>
```

### Defining parameters in tasks

Allow your task to accept parameters as either environment variables or as a JSON hash on standard input.

Tasks can receive input as either environment variables, a JSON hash on standard input, or as PowerShell arguments. By default, the task runner submits parameters as both environment variables and as JSON on stdin.

If your task needs to receive parameters only in a certain way, such as stdin only, you can set the input method in your task metadata. For Windows tasks, it’s usually better to use tasks written in PowerShell. See the related topic about task metadata for information about setting the input method.

Environment variables are the easiest way to implement parameters, and they work well for simple JSON types such as strings and numbers. For arrays and hashes, use structured input instead because parameters with undefined values...
(nil, undef) passed as environment variables have the String value null. For more information, see Structured input and output on page 487.

To add parameters to your task as environment variables, pass the argument prefixed with the Puppet task prefix PT_.

For example, to add a message parameter to your task, read it from the environment in task code as PT_message. When the user runs the task, they can specify the value for the parameter on the command line as message=hello, and the task runner submits the value hello to the PT_message variable.

```bash
#!/usr/bin/env bash
echo your message is $PT_message
```

**Defining parameters in Windows**

For Windows tasks, you can pass parameters as environment variables, but it's easier to write your task in PowerShell and use named arguments. By default tasks with a .ps1 extension use PowerShell standard argument handling.

For example, this PowerShell task takes a process name as an argument and returns information about the process. If no parameter is passed by the user, the task returns all of the processes.

```powershell
[CmdletBinding()]
Param(  [Parameter(Mandatory = $False)]
  [String]
  $Name  )

if ($Name -eq $null -or $Name -eq "") {
  Get-Process
} else {
  $processes = Get-Process -Name $Name
  $result = @()
  foreach ($process in $processes) {
    $result += @{
      "Name" = $process.ProcessName;
      "CPU" = $process.CPU;
      "Memory" = $process.WorkingSet;
      "Path" = $process.Path;
      "Id" = $process.Id
    }
  }
  if ($result.Count -eq 1) {
    ConvertTo-Json -InputObject $result[0] -Compress
  } elseif ($result.Count -gt 1) {
    ConvertTo-Json -InputObject @{"_items" = $result} -Compress
  }
}

To pass parameters in your task as environment variables (PT_parameter), you must set input_method in your task metadata to environment. To run Ruby tasks on Windows, the Puppet agent must be installed on the target nodes.

**Returning errors in tasks**

To return a detailed error message if your task fails, include an Error object in the task's result.

When a task exits non-zero, the task runner checks for an error key ("_error"). If one is not present, the task runner generates a generic error and adds it to the result. If there is no text on stdout but text is present on stderr, the stderr text is included in the message.

```json
{  "_error": {
    "msg": "Task exited 1:\nSomething on stderr",
```

© 2020 Puppet, Inc.
An error object includes the following keys:

msg
A human readable string that appears in the UI.

kind
A standard string for machines to handle. You can share kinds between your modules or namespace kinds per module.

details
An object of structured data about the tasks.

Tasks can provide more details about the failure by including their own error object in the result at _error.

```ruby
#!/opt/puppetlabs/puppet/bin/ruby
require 'json'

begin
  params = JSON.parse(STDIN.read)
  result = {}
  result['result'] = params['dividend'] / params['divisor']
rescue ZeroDivisionError
  result[:_error] = { msg: "Cannot divide by zero",
    kind: "puppetlabs-example_modules/dividebyzero",
    details: { divisor: divisor }
  }
rescue Exception => e
  result[:_error] = { msg: e.message,
    kind: "puppetlabs-example_modules/unknown",
    details: { class: e.class.to_s },
  }
end
puts result.to_json
```

Structured input and output

If you have a task that has many options, returns a lot of information, or is part of a task plan, consider using structured input and output with your task.

The task API is based on JSON. Task parameters are encoded in JSON, and the task runner attempts to parse the output of the tasks as a JSON object.

The task runner can inject keys into that object, prefixed with __. If the task does not return a JSON object, the task runner creates one and places the output in an _output key.

Structured input
For complex input, such as hashes and arrays, you can accept structured JSON in your task.

By default, the task runner passes task parameters as both environment variables and as a single JSON object on stdin. The JSON input allows the task to accept complex data structures.

To accept parameters as JSON on stdin, set the params key to accept JSON on stdin.

```ruby
#!/opt/puppetlabs/puppet/bin/ruby
```
require 'json'

params = JSON.parse(STDIN.read)

exitcode = 0
params['files'].each do |filename|
  begin
    FileUtils.touch(filename)
    puts "updated file #{filename}"
  rescue
    exitcode = 1
    puts "couldn't update file #{filename}"
  end
end
exit exitcode

If your task accepts input on stdin it should specify "input_method": "stdin" in its metadata.json file, or it might not work with sudo for some users.

**Returning structured output**
To return structured data from your task, print only a single JSON object to stdout in your task.

Structured output is useful if you want to use the output in another program, or if you want to use the result of the task in a Puppet task plan.

```bash
#!/usr/bin/env python
import json
import sys
minor = sys.version_info
result = { "major": sys.version_info.major, "minor": sys.version_info.minor }
json.dump(result, sys.stdout)
```

**Converting scripts to tasks**
To convert an existing script to a task, you can either write a task that wraps the script or you can add logic in your script to check for parameters in environment variables.

If the script is already installed on the target nodes, you can write a task that wraps the script. In the task, read the script arguments as task parameters and call the script, passing the parameters as the arguments.

If the script isn't installed or you want to make it into a cohesive task so that you can manage its version with code management tools, add code to your script to check for the environment variables, prefixed with PT_, and read them instead of arguments.

⚠️ **CAUTION:** For any tasks that you intend to use with PE and assign RBAC permissions, make sure the script safely handles parameters or validate them to prevent shell injection vulnerabilities.

Given a script that accepts positional arguments on the command line:

```bash
version=$1
[ -z "$version" ] && echo "Must specify a version to deploy && exit 1
if [ -z "$2" ]; then
  filename=$2
else
  filename=~/.myfile
fi
```
To convert the script into a task, replace this logic with task variables:

```bash
version=${PT_version} #no need to validate if we use metadata
if [ -z "${PT_filename}" ]; then
  filename=${PT_filename}
else
  filename=~/myfile
fi
```

### Wrapping an existing script

If a script is not already installed on targets and you don’t want to edit it, for example if it’s a script someone else maintains, you can wrap the script in a small task without modifying it.

**CAUTION:** For any tasks that you intend to use with PE and assign RBAC permissions, make sure the script safely handles parameters or validate them to prevent shell injection vulnerabilities.

Given a script, `myscript.sh`, that accepts 2 positional args, `filename` and `version`:

1. Copy the script to the module's `files/` directory.
2. Create a metadata file for the task that includes the parameters and file dependency.
   ```json
   { "input_method": "environment", "parameters": { "filename": { "type": "String[1]" }, "version": { "type": "String[1]" } }, "files": [ "script_example/files/myscript.sh" ] }
   ```
3. Create a small wrapper task that reads environment variables and calls the task.
   ```bash
   #!/usr/bin/env bash
   set -e
   script_file="${PT__installdir}/script_example/files/myscript.sh" # If this task is going to be run from windows nodes
   the wrapper must make sure it's executable
   chmod +x $script_file
   commandline=""${script_file}" "${PT_filename}" "${PT_version}"" # If the stderr output of the script is important redirect it to stdout.
   "${commandline[@]}" 2>&1
   ```

### Supporting no-op in tasks

Tasks support no-operation functionality, also known as no-op mode. This function shows what changes the task would make, without actually making those changes.

No-op support allows a user to pass the `--noop` flag with a command to test whether the task will succeed on all targets before making changes.

To support no-op, your task must include code that looks for the `_noop` metaparameter. No-op is supported only in Puppet Enterprise.

If the user passes the `--noop` flag with their command, this parameter is set to `true`, and your task must not make changes. You must also set `supports_noop` to `true` in your task metadata or the task runner will refuse to run the task in noop mode.

**No-op metadata example**

```json
{
  "description": "Write content to a file.",
  "supports_noop": true,
  "parameters": {
    "filename": { 
      "description": "the file to write to",
      "type": "String[1]"
    },
    "content": {
      "description": "The content to write",
```
No-op task example

#!/usr/bin/env python
import json
import os
import sys

params = json.load(sys.stdin)
filename = params['filename']
content = params['content']
oop = params.get('_noop', False)

exitcode = 0

def make_error(msg):
    error = {
        "_error": {
            "kind": "file_error",
            "msg": msg,
            "details": {}},
    }
    return error

try:
    if noop:
        path = os.path.abspath(os.path.join(filename, os.pardir))
        file_exists = os.access(filename, os.F_OK)
        file_writable = os.access(filename, os.W_OK)
        path_writable = os.access(path, os.W_OK)

        if path_writable == False:
            exitcode = 1
            result = make_error("Path %s is not writable" % path)
        elif file_exists == True and file_writable == False:
            exitcode = 1
            result = make_error("File %s is not writable" % filename)
        else:
            result = { "success": True , '_noop': True }
    else:
        with open(filename, 'w') as fh:
            fh.write(content)
            result = { "success": True }
except Exception as e:
    exitcode = 1
    result = make_error("Could not open file %s: %s" % (filename, str(e)))
print(json.dumps(result))
exit(exitcode)

Task metadata

Task metadata files describe task parameters, validate input, and control how the task runner executes the task.

Your task must have metadata to be published and shared on the Forge. Specify task metadata in a JSON file with the naming convention <TASKNAME>.json. Place this file in the module’s ./tasks folder along with your task file.
For example, the module puppetlabs-mysql includes the mysql::sql task with the metadata file, sql.json.

```json
{
  "description": "Allows you to execute arbitrary SQL",
  "input_method": "stdin",
  "parameters": {
    "database": {
      "description": "Database to connect to",
      "type": "Optional[String[1]]"
    },
    "user": {
      "description": "The user",
      "type": "Optional[String[1]]"
    },
    "password": {
      "description": "The password",
      "type": "Optional[String[1]]",
      "sensitive": true
    },
    "sql": {
      "description": "The SQL you want to execute",
      "type": "String[1]"
    }
  }
}
```

**Adding parameters to metadata**

To document and validate task parameters, add the parameters to the task metadata as JSON object, `parameters`.

If a task includes `parameters` in its metadata, the task runner rejects any parameters input to the task that aren't defined in the metadata.

In the `parameter` object, give each parameter a description and specify its Puppet type. For a complete list of types, see the types documentation.

For example, the following code in a metadata file describes a `provider` parameter:

```json
"provider": {
  "description": "The provider to use to manage or inspect the service, defaults to the system service manager",
  "type": "Optional[String[1]]"
}
```

**Define default parameters**

You can define default task parameters, which are supplied to a task run even if the user does not specify a value for the parameter.

For example, the default location for this `log_location` parameter is `/var/log/puppetlabs`

```json
"log_location": {
  "type": "String",
  "description": "The location the log will be stored in",
  "default": "/var/log/puppetlabs"
}
```

**Note:** Parameters with defaults are considered optional.
Define sensitive parameters

You can define task parameters as sensitive, for example, passwords and API keys. These values are masked when they appear in logs and API responses. When you want to view these values, set the log file to level: debug.

To define a parameter as sensitive within the JSON metadata, add the "sensitive": true property.

```json
{
    "description": "This task has a sensitive property denoted by its metadata",
    "input_method": "stdin",
    "parameters": {
        "user": {
            "description": "The user",
            "type": "String[1]"
        },
        "password": {
            "description": "The password",
            "type": "String[1]",
            "sensitive": true
        }
    }
}
```

Task metadata reference

The following table shows task metadata keys, values, and default values.

Table 2: Task metadata

<table>
<thead>
<tr>
<th>Metadata key</th>
<th>Description</th>
<th>Value</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;description&quot;</td>
<td>A description of what the task does.</td>
<td>String</td>
<td>None</td>
</tr>
<tr>
<td>&quot;input_method&quot;</td>
<td>What input method the task runner should use to pass parameters to the task.</td>
<td></td>
<td>Both environment and stdin unless .ps1 tasks, in which case powershell</td>
</tr>
<tr>
<td>&quot;parameters&quot;</td>
<td>The parameters or input the task accepts listed with a puppet type string and optional description. See adding parameters to metadata for usage information.</td>
<td>Array of objects describing each parameter</td>
<td>None</td>
</tr>
<tr>
<td>&quot;puppet_task_version&quot;</td>
<td>The version of the spec used.</td>
<td>Integer</td>
<td>1 (This is the only valid value.)</td>
</tr>
<tr>
<td>&quot;supports_noop&quot;</td>
<td>Whether the task supports no-op mode. Required for the task to accept the --noop option on the command line.</td>
<td>Boolean</td>
<td>False</td>
</tr>
<tr>
<td>Metadata key</td>
<td>Description</td>
<td>Value</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
<td>-------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>&quot;implementations&quot;</td>
<td>A list of task implementations and the requirements used to select one to run. See Cross-platform tasks on page 480 for usage information.</td>
<td>Array of Objects describing each implementation</td>
<td>None</td>
</tr>
<tr>
<td>&quot;files&quot;</td>
<td>A list of files to be provided when running the task, addressed by module. See Sharing task code on page 482 for usage information.</td>
<td>Array of Strings</td>
<td>None</td>
</tr>
</tbody>
</table>

**Task metadata types**

Task metadata can accept most Puppet data types.

**Restriction:**

Some types supported by Puppet can not be represented as JSON, such as Hash[Integer, String], Object, or Resource. These should not be used in tasks, because they can never be matched.

**Table 3: Common task data types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Accepts any string.</td>
</tr>
<tr>
<td>String[1]</td>
<td>Accepts any non-empty string (a String of at least length 1).</td>
</tr>
<tr>
<td>Enum[choice1, choice2]</td>
<td>Accepts one of the listed choices.</td>
</tr>
<tr>
<td>Pattern[/\A\w+\Z/]</td>
<td>Accepts Strings matching the regex /\w+/ or non-empty strings of word characters.</td>
</tr>
<tr>
<td>Integer</td>
<td>Accepts integer values. JSON has no Integer type so this can vary depending on input.</td>
</tr>
<tr>
<td>Optional[String[1]]</td>
<td>Optional makes the parameter optional and permits null values. Tasks have no required nullable values.</td>
</tr>
<tr>
<td>Array[String]</td>
<td>Matches an array of strings.</td>
</tr>
<tr>
<td>Hash</td>
<td>Matches a JSON object.</td>
</tr>
<tr>
<td>Variant[Integer, Pattern[/\A\d+\Z/]]</td>
<td>Matches an integer or a String of an integer</td>
</tr>
<tr>
<td>Boolean</td>
<td>Accepts Boolean values.</td>
</tr>
</tbody>
</table>

**Specifying parameters**

Parameters for tasks can be passed to the bolt command as CLI arguments or as a JSON hash.

To pass parameters individually to your task or plan, specify the parameter value on the command line in the format parameter=value. Pass multiple parameters as a space-separated list. Bolt attempts to parse each parameter value as JSON and compares that to the parameter type specified by the task or plan. If the parsed value matches the type, it is used; otherwise, the original string is used.
For example, to run the `mysql::sql` task to show tables from a database called `mydatabase`:

```bash
bolt task run mysql::sql database=mydatabase sql="SHOW TABLES" --nodes neptune --modules ~/modules
```

To pass a string value that is valid JSON to a parameter that would accept both quote the string. For example to pass the string `true` to a parameter of type `Variant[String, Boolean]` use `foo="true"`. To pass a String value wrapped in " quote and escape it 'string="val"'. Alternatively, you can specify parameters as a single JSON object with the `--params` flag, passing either a JSON object or a path to a parameter file.

To specify parameters as JSON, use the `--params` flag followed by the JSON: `--params '{"name": "openssl"}'`

To set parameters in a file, specify parameters in JSON format in a file, such as `params.json`. For example, create a `params.json` file that contains the following JSON:

```json
{
   "name": "openssl"
}
```

Then specify the path to that file (starting with an at symbol, @) on the command line with the `--params` flag: `--params @params.json`

### Writing plans

Plans allow you to run more than one task with a single command, compute values for the input to a task, process the results of tasks, or make decisions based on the result of running a task.

Write plans in the Puppet language, giving them a .pp extension, and placing them in the module's /plans directory.

Plans can use any combination of Bolt functions or built-in Puppet functions.

- **Plan caveats and limitations** on page 474
  Some plan language and features are not available in PE or have some caveats.
- **Writing plans in YAML** on page 497
  YAML plans run a list of steps in order, which allows you to define simple workflows. Steps can contain embedded Puppet code expressions to add logic where necessary.
- **Writing plans in Puppet Language** on page 511
  Plans allow you to run more than one task with a single command, compute values for the input to a task, process the results of tasks, or make decisions based on the result of running a task.

### Plan caveats and limitations

Some plan language and features are not available in PE or have some caveats.

#### Bolt modules are not included

The following modules that come pre-installed with open source Bolt are not available by default in PE:

- `aggregate`
- `canary`
- `puppetdb_fact`
- `ruby_task_helper`
- `python_task_helper`
- `facts`
  - The PE equivalent of `facts` is `factor_task`
• puppet_agent
  • The PE equivalent of puppet_agent is pe_bootstrap

**Plan language functions**

The following Bolt plan functions will not work in PE and using them will cause a plan to fail:

• file::read
• file::write
• file::readable
• file::exists
• set_feature
• add_to_group
• set_config

**Apply blocks**

The apply feature, including apply_prep, only works only for targets using the PXP agent and the PCP transport. It will fail on targets connected via SSH or WinRM.

**Target groups**

Support for target groups is unavailable in PE. Using add_to_group will cause a plan to fail and referencing a group name in get_targets will not return any nodes. When using get_targets you **must** reference either node certnames or supply a PuppetDB query.

Here is an example of a plan using get targets with node certnames:

```r
plan example::get_targets_example () {
  $nodes = get_targets(['node1.example.com', 'node2.example.com'])
  run_command('whoami', $nodes)
}
```

**Target features**

Support for target features is unavailable in PE. Using set_feature will cause a plan to fail and referencing a target object’s features list will always return an empty array.

Here is an example of a plan that would return an empty features list:

```r
plan example::empty_features_example (TargetSpec $node) {
  return get_target($node).features()
}
```

**Target configuration**

While you can set up node transport configuration through the PE inventory for nodes to use SSH or WinRM, plans in PE do not support setting or changing the configuration settings for targets from within a plan. Using the set_config function in a plan will cause a plan to fail and referencing a target object’s configuration hash will always return an empty hash.

The use of URIs in a target name to override the transport is also not supported. All references to targets (i.e. when using get_targets) must be either PuppetDB queries or valid certnames that are already in the PE inventory.

Here is an example of a plan that uses get_targets correctly:

```r
plan example::get_targets_example () {
  ## NOTE! If you used ssh://node1.example.com as the first entry, this plan
  ## would fail!
```
$nodes = get_targets(['node1.example.com', 'node2.example.com'])
run_command('whoami', $nodes)
}

__run_as options in plan functions__

Plans in PE does not support the `_run_as` parameter for changing the user that accesses hosts or executes actions. If this parameter is supplied to any plan function, the plan will execute but the user will not change.

For example, the following plan will succeed, but will not run as other_user:

plan example::run_as_example (TargetSpec $nodes) {
  run_command('whoami', $nodes, _run_as => 'other_user')
}

The localhost target

The special target `localhost` is not available for plans in PE. Using `localhost` anywhere in a plan will result in a plan failure. If you need to run a plan on the PE master host, use the master's certname to reference it.

For example, you can use the following plan for PE master host `my-pe-master.company.com`:

plan example::referencing_the_master() {
  # Note that if you tried to use `localhost` instead of `my-pe-master` this plan would fail!
  run_command('whoami', 'my-pe-master.company.com')
}

Standard Puppet log functions

Puppet's built-in logging functions, like `notice` and `warn`, will not log anywhere. Plans with those functions will still work, but the logging messages will not appear.

If you need to use a logging function in your plan, the `out::message()` plan function will write an event to the orchestrator's event stream.

For example, the following will log the message correctly to the event stream:

plan example::logging() {
  out::message("This will output to the orchestrator event stream")
}

This will not log any messages:

plan example::bad_logging() {
  # neither of the following will output any messages anywhere
  notice("this will go nowhere!")
  warn("this will also go nowhere!")
}

Script and file sources

When using `run_script` or `download_file`, the source location for the files must be from a module that uses a modulename/filename selector for a file or directory in `$MODULEROOT/files`. PE does not support file sources that reference absolute paths.

Here is an example of a module structure and a plan that correctly uses the modulename/filename selector:

eexample/
### files
### Code deployment for plans

For plans in PE to work, you must have code manager enabled to deploy code to your master.

Masters will now deploy a second codedir for plans to load code from. The second code location on masters have some effects on standard module functionality:

- Installation modules using the `puppet module install` command will not work for plans because the puppet module tool will not install to the secondary location for plans. The `puppet module install` command will still work for normal Puppet code executed and compiled from Puppet Server.
- A `$modulepath` configuration that uses fully qualified paths might not work for plans if they reference the standard `/etc/puppetlabs/code` location. We recommend using relative paths in `$modulepath`.

### Writing plans in YAML

YAML plans run a list of steps in order, which allows you to define simple workflows. Steps can contain embedded Puppet code expressions to add logic where necessary.

**Note:** YAML plans are an experimental feature and might experience breaking changes in future minor releases.

### Naming plans

It is important to name plans correctly according to the module name, file name, and path to ensure easy code readability.

Place plan files in your module’s `.plans` directory, using these file extensions:

- Puppet plans — `.pp`
- YAML plans — `.yaml`, not `.yml`

Plan names are composed of two or more name segments, indicating:

- The name of the module the plan is located in.
- The name of the plan file, without the extension.
- The path within the module, if the plan is in a subdirectory of `.plans`.

For example, given a module called `mymodule` with a plan defined in `./mymodule/plans/myplan.pp`, the plan name is `mymodule::myplan`.

A plan defined in `./mymodule/plans/service/myplan.pp` would be `mymodule::service::myplan`. This name is how you refer to the plan when you run commands.

The plan filename `init` is special: the plan it defines is referenced using the module name only. For example, in a module called `mymodule`, the plan defined in `init.pp` is the `mymodule` plan.

Avoid giving plans the same names as constructs in the Puppet language. Although plans do not share their namespace with other language constructs, giving plans these names makes your code difficult to read.

Each plan name segment must begin with a lowercase letter and:

- May include lowercase letters.
- May include digits.
- May include underscores.
- Must not be a reserved word.
- Must not have the same name as any Puppet data types.
Namespace segments must match the following regular expression `\A[a-z][a-z0-9_]*\Z`

**RBAC considerations for writing plans**

Take user permissions into consideration when writing plans by understanding how RBAC for plans works.

RBAC for plans is separate from RBAC for individual tasks. This means that a user can be excluded from running a certain task, but still have permission to run a plan that contains that task. Setting one permission does not affect the other.

This structure allows you to write plans with more robust, custom control over task permissions. Instead of allowing a user free rein to run a task that can potentially damage your infrastructure under the right conditions, you can wrap a task in a plan and only allow them to run it under circumstances you can control.

For example, say you are configuring permissions for a new user and allow them to run the plan `infra::upgrade_git`:

```puppet
plan infra::upgrade_git (TargetSpec $nodes, Integer $version,)
    {
        run_task('package', $nodes, name => 'git', action => 'upgrade', version => $version)
    }
```

Within this plan, they can run the `package` task, but can only interact with the `git` package. The plan does not allow them to use any other parameters for the `package` task.

Even though they can run this plan, they do not have access to individually run the `package` task outside of this plan unless you grant them permission to do so. In that case, they would have the option to add any parameters they want to the task.

**Use parameter types to fine-tune access**

Writing parameter types into plan code provides even more control. In the `upgrade_git` example above, the plan only provides access to the `git` package, but the user can choose whatever version of `git` they want.

Let's say there are known vulnerabilities in some versions of the `git` package and you are concerned with your new user having the ability to use the versions you deem unsafe. You can use parameter types like `Enum` to restrict the version parameter to versions that are safe enough for deployment.

In this example, the `Enum` restricts the `$version` parameter to versions `1:2.17.0-1ubuntu1` and `1:2.17.1-1ubuntu0.4` only:

```puppet
plan infra::upgrade_git (TargetSpec $nodes, Enum['1:2.17.0-1ubuntu1', '1:2.17.1-1ubuntu0.4'] $version,)
    {
        run_task('package', $nodes, name => 'git', action => 'upgrade', version => $version)
    }
```

Any user attempting to run this plan must choose one of these versions for the plan to run.

You can also use PuppetDB queries to select parameter types. Using the same example, let's say you need to restrict the nodes that `infra::upgrade_git` can run on. Use a PuppetDB query to identify which nodes get selected for the `git` upgrade. It should look something like this:

```puppet
plan infra::upgrade_git (Enum['1:2.17.0-1ubuntu1', '1:2.17.1-1ubuntu0.4'] $version,)
    {  
        # Use puppetdb to find the nodes from the "other" team's web cluster
        $query = [from, nodes, [':=', [fact, cluster], "other_team"]]
    }
```
Using these ideas, you can write powerful plans that give users exactly what they need without giving them the keys to the kingdom.

Plan structure
YAML plans contain a list of steps with optional parameters and results.

YAML maps accept these keys:

- steps: The list of steps to perform
- parameters: (Optional) The parameters accepted by the plan
- return: (Optional) The value to return from the plan

Steps key
The steps key is an array of step objects, each of which corresponds to a specific action to take.

When the plan runs, each step is executed in order. If a step fails, the plan halts execution and raises an error containing the result of the step that failed.

Steps use these fields:

- name: A unique name that can be used to refer to the result of the step later
- description: (Optional) An explanation of what the step is doing

Other available keys depend on the type of step.

Command step
Use a command step to run a single command on a list of targets and save the results, containing stdout, stderr, and exit code.

The step fails if the exit code of any command is non-zero.

Command steps use these fields:

- command: The command to run
- target: A target or list of targets to run the command on

For example:

    steps:
      - command: hostname -f
        target:
          - web1.example.com
          - web2.example.com
          - web3.example.com
        description: "Get the webserver hostnames"

Task step
Use a task step to run a Bolt task on a list of targets and save the results.

Task steps use these fields:

- task: The task to run
- target: A target or list of targets to run the task on
- parameters: (Optional) A map of parameter values to pass to the task
For example:

```
steps:
  - task: package
    target:
      - web1.example.com
      - web2.example.com
      - web3.example.com
    description: "Check the version of the openssl package on the webbservers"
    parameters:
      action: status
      name: openssl
```

**Script step**

Use a script step to run a script on a list of targets and save the results.

The script must be in the `files/` directory of a module. The name of the script must be specified as `<modulename>/path/to/script`, omitting the `files` directory from the path.

Script steps use these fields:

- **script**: The script to run
- **target**: A target or list of targets to run the script on
- **arguments**: (Optional) An array of command-line arguments to pass to the script

For example:

```
steps:
  - script: mymodule/check_server.sh
    target:
      - web1.example.com
      - web2.example.com
      - web3.example.com
    description: "Run mymodule/files/check_server.sh on the webbservers"
    arguments:
      - "#/index.html"
      - 60
```

**File upload step**

Use a file upload step to upload a file to a specific location on a list of targets.

The file to upload must be in the `files/` directory of a Puppet module. The source for the file must be specified as `<modulename>/path/to/file`, omitting the `files` directory from the path.

File upload steps use these fields:

- **source**: The location of the file to be uploaded
- **destination**: The location to upload the file to

For example:

```
steps:
  - source: mymodule/motd.txt
    destination: /etc/motd
    target:
      - web1.example.com
      - web2.example.com
      - web3.example.com
    description: "Upload motd to the webbservers"
```
**Plan step**

Use a plan step to run another plan and save its result.

Plan steps use these fields:

- `plan`: The name of the plan to run
- `parameters`: (Optional) A map of parameter values to pass to the plan

For example:

```yaml
steps:
  - plan: facts
description: "Gather facts for the webservers using the built-in facts plan"
  parameters:
    nodes:
      - web1.example.com
      - web2.example.com
      - web3.example.com
```

**Resources step**

Use a resources step to apply a list of Puppet resources. A resource defines the desired state for part of a target. Bolt ensures each resource is in its desired state. Like the steps in a plan, if any resource in the list fails, the rest are skipped.

For each resources step, Bolt executes the `apply_prep` plan function against the targets specified with the `targets` field. For more information about `apply_prep` see the Applying manifest block section.

Resources steps use these fields:

- `resources`: An array of resources to apply
- `target`: A target or list of targets to apply the resources on

Each resource is a YAML map with a type and title, and optionally a `parameters` key. The resource type and title can either be specified separately with the `type` and `title` keys, or can be specified in a single line by using the type name as a key with the title as its value.

For example:

```yaml
steps:
  - resources:
      # This resource is type 'package' and title 'nginx'
      - package: nginx
        parameters:
          ensure: latest
      # This resource is type 'service' and title 'nginx'
      - type: service
        title: nginx
        parameters:
          ensure: running
        target:
          - web1.example.com
          - web2.example.com
          - web3.example.com
      description: "Set up nginx on the webservers"
```

**Parameters key**

Plans accept parameters with the `parameters` key. The value of `parameters` is a map, where each key is the name of a parameter and the value is a map describing the parameter.

Parameter values can be referenced from steps as variables.
Parameters use these fields:

- **type**: (Optional) A valid Puppet data type. The value supplied must match the type or the plan fails.
- **default**: (Optional) Used if no value is given for the parameter
- **description**: (Optional)

For example, this plan accepts a `load_balancer` name as a string, two sets of nodes called `frontends` and `backends`, and a `version` string:

```yaml
parameters:
  # A simple parameter definition doesn't need a type or description
  load_balancer:
    frontends:
      type: TargetSpec
      description: "The frontend web servers"
    backends:
      type: TargetSpec
      description: "The backend application servers"
  version:
    type: String
    description: "The new application version to deploy"
```

**How strings are evaluated**

The behavior of strings is defined by how they're written in the plan.

- **'single-quoted strings'** are treated as string literals without any interpolation.
- **"double-quoted strings"** are treated as Puppet language double-quoted strings with variable interpolation.
- **block-style strings** are treated as expressions of arbitrary Puppet code. Note the string itself must be on a new line after the `|` character.
- **bare strings** are treated dynamically based on their content. If they begin with a $, they're treated as Puppet code expressions. Otherwise, they're treated as YAML literals.

Here's an example of different kinds of strings in use:

```yaml
parameters:
  message:
    type: String
    default: "hello"

steps:
- eval: hello
  description: 'This will evaluate to: hello'
- eval: $message
  description: 'This will evaluate to: $message'
- eval: '$message'
  description: 'This will evaluate to: $message'
- eval: ${message} world
  description: 'This will evaluate to: hello world'
- eval: ${message, $message, $message}.join(" ")
  description: 'This will evaluate to: hello hello hello'
```

**Plan caveats and limitations**

Some plan language and features are not available in PE or have some caveats.

**Bolt modules are not included**

The following modules that come pre-installed with open source Bolt are not available by default in PE:

- **aggregate**
• canary
• puppetdb_fact
• ruby_task_helper
• python_task_helper
• facts
  • The PE equivalent of facts is factor_task
• puppet_agent
  • The PE equivalent of puppet_agent is pe_bootstrap

Plan language functions

The following Bolt plan functions will not work in PE and using them will cause a plan to fail:

• file::read
• file::write
• file::readable
• file::exists
• set_feature
• add_to_group
• set_config

Apply blocks

The apply feature, including apply_prep, only works only for targets using the PXP agent and the PCP transport. It will fail on targets connected via SSH or WinRM.

Target groups

Support for target groups is unavailable in PE. Using add_to_group will cause a plan to fail and referencing a group name in get_targets will not return any nodes. When using get_targets you must reference either node certnames or supply a PuppetDB query.

Here is an example of a plan using get targets with node certnames:

```plan
def example::get_targets_example () {  
  $nodes = get_targets(['node1.example.com', 'node2.example.com'])  
  run_command('whoami', $nodes)  
}
```

Target features

Support for target features is unavailable in PE. Using set_feature will cause a plan to fail and referencing a target object’s features list will always return an empty array.

Here is an example of a plan that would return an empty features list:

```plan
def example::empty_features_example (TargetSpec $node) {  
  return get_target($node).features()  
}
```

Target configuration

While you can set up node transport configuration through the PE inventory for nodes to use SSH or WinRM, plans in PE do not support setting or changing the configuration settings for targets from within a plan. Using the set_config function in a plan will cause a plan to fail and referencing a target object’s configuration hash will always return an empty hash.
The use of URIs in a target name to override the transport is also not supported. All references to targets (i.e. when using `get_targets`) must be either PuppetDB queries or valid certnames that are already in the PE inventory.

Here is an example of a plan that uses `get_targets` correctly:

```puppet
plan example::get_targets_example () {
  ## NOTE! If you used ssh://node1.example.com as the first entry, this plan would fail!
  $nodes = get_targets(['node1.example.com', 'node2.example.com'])
  run_command('whoami', $nodes)
}
```

**_run_as options in plan functions**

Plans in PE does not support the `_run_as` parameter for changing the user that accesses hosts or executes actions. If this parameter is supplied to any plan function, the plan will execute but the user will not change.

For example, the following plan will succeed, but will not run as `other_user`:

```puppet
plan example::run_as_example (TargetSpec $nodes) {
  run_command('whoami', $nodes, _run_as => 'other_user')
}
```

**The localhost target**

The special target `localhost` is not available for plans in PE. Using `localhost` anywhere in a plan will result in a plan failure. If you need to run a plan on the PE master host, use the master's certname to reference it.

For example, you can use the following plan for PE master host `my-pe-master.company.com`:

```puppet
plan example::referencing_the_master(){
  # Note that if you tried to use `localhost` instead of `my-pe-master` this plan would fail!
  run_command('whoami', 'my-pe-master.company.com')
}
```

**Standard Puppet log functions**

Puppet's built-in logging functions, like `notice` and `warn`, will not log anywhere. Plans with those functions will still work, but the logging messages will not appear.

If you need to use a logging function in your plan, the `out::message()` plan function will write an event to the orchestrator's event stream.

For example, the following will log the message correctly to the event stream:

```puppet
plan example::logging(){
  out::message("This will output to the orchestrator event stream")
}
```

This will not log any messages:

```puppet
plan example::bad_logging(){
  # neither of the following will output any messages anywhere
  notice("this will go nowhere!")
  warn("this will also go nowhere!")
}
```

© 2020 Puppet, Inc.
Script and file sources

When using `run_script` or `download_file`, the source location for the files **must** be from a module that uses a modulename/filename selector for a file or directory in `$MODULEROOT/files`. PE does not support file sources that reference absolute paths.

Here is an example of a module structure and a plan that correctly uses the modulename/filename selector:

```plaintext
eexample/
    ### files
    ###my_script.sh
    ### plans
    ###run_script_example.pp

plan example::run_script_example (TargetSpec $nodes) {
    run_script('example/my_script.sh', $nodes)
}
```

Code deployment for plans

For plans in PE to work, you must have code manager enabled to deploy code to your master.

Masters will now deploy a second codedir for plans to load code from. The second code location on masters have some effects on standard module functionality:

- Installation modules using the `puppet module install` command will not work for plans because the puppet module tool will not install to the secondary location for plans. The `puppet module install` command will still work for normal Puppet code executed and compiled from Puppet Server.
- A `$modulepath` configuration that uses fully qualified paths might not work for plans if they reference the standard `/etc/puppetlabs/code` location. We recommend using relative paths in `$modulepath`.

Using variables and simple expressions

The simplest way to use a variable is to reference it directly by name. For example, this plan takes a parameter called `nodes` and passes it as the target list to a step:

```plaintext
parameters:
    nodes:
        type: TargetSpec

steps:
    - command: hostname -f
      target: $nodes
```

Variables can also be interpolated into string values. The string must be double-quoted to allow interpolation. For example:

```plaintext
parameters:
    username:
        type: String

steps:
    - task: echo
      message: "hello ${username}"  
      target: $nodes
```

Many operations can be performed on variables to compute new values for step parameters or other fields.
Indexing arrays or hashes

You can retrieve a value from an Array or a Hash using the [] operator. This operator can also be used when interpolating a value inside a string.

```plaintext
parameters:
users:
  # Array[String] is a Puppet data type representing an array of strings
type: Array[String]

steps:
- task: user::add
target: 'host.example.com'
parameters:
  name: $users[0]
- task: echo
target: 'host.example.com'
parameters:
  message: "hello ${users[0]}"
```

Calling functions

You can call a built-in Bolt function or Puppet function to compute a value.

```plaintext
parameters:
users:
type: Array[String]

steps:
- task: user::add
  target: 'host.example.com'
parameters:
  name: $users.first
- task: echo
  target: 'host.example.com'
parameters:
  message: "hello ${users.join(',')}
```

Using code blocks

Some Puppet functions take a block of code as an argument. For instance, you can filter an array of items based on the result of a block of code.

The result of the filter function is an array here, not a string, because the expression isn't inside quotes

```plaintext
parameters:
numbers:
type: Array[Integer]

steps:
- task: sum
description: "add up the numbers > 5"
parameters:
  indexes: $numbers.filter |$num| { $num > 5 }
```

Connecting steps

You can connect multiple steps by using the result of one step to compute the parameters for another step.

name key

The name key makes its results available to later steps in a variable with that name.
This example uses the `map` function to get the value of `stdout` from each command result and then joins them into a single string separated by commas.

```yaml
parameters:
  nodes:
    type: TargetSpec

steps:
- name: hostnames
  command: hostname -f
  target: $nodes
- task: echo
  parameters:
    message: $hostnames.map |$hostname_result|
    { $hostname_result['stdout'] }.join(',')
```

**eval step**

The `eval` step evaluates an expression and saves the result in a variable. This is useful to compute a variable to use multiple times later.

```yaml
parameters:
  count:
    type: Integer

steps:
- name: double_count
  eval: $count * 2
- task: echo
  target: web1.example.com
  parameters:
    message: "The count is ${count}, and twice the count is ${double_count}"
```

**Returning results**

You can return a result from a plan by setting the `return` key at the top level of the plan. When the plan finishes, the `return` key is evaluated and returned as the result of the plan. If no `return` key is set, the plan returns `undef`.

```yaml
steps:
- name: hostnames
  command: hostname -f
  target: $nodes

return: $hostnames.map |$hostname_result|
    { $hostname_result['stdout'] }
```

**Applying manifest blocks from a plan**

You can apply manifest blocks to remote systems during plan execution using the `apply` and `apply_prep` functions.

Manifest blocks require facts to compile. If your plan includes a manifest block, use the `apply_prep` function in your plan before your manifest block. The `apply_prep` function syncs and caches plugins and gathers facts by running `facter`, making the facts available to the manifest block.

For example:

```bash
apply_prep($target)
apply($target) { notify { foo: } }
```

**Note:** You can only use `apply` and `apply_prep` on nodes connected via PCP.
**apply options**

The apply function supports the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_catch_errors</td>
<td>true</td>
<td>Returns a ResultSet, including failed results, rather than failing the plan.</td>
</tr>
<tr>
<td>_description</td>
<td>none</td>
<td>Adds a description to the apply block.</td>
</tr>
<tr>
<td>_noop</td>
<td>true</td>
<td>Applies the manifest block in no-operation mode, returning a report of changes it would make but does not take action</td>
</tr>
</tbody>
</table>

For example:

```puppet
# Preview installing docker as root on $targets.
apply($targets, _catch_errors => true, _noop => true) {
    include 'docker'
}
```

**How manifest blocks are applied**

PE compiles the code in your manifest block into a catalog in this order.

1. Facts gathered from the targets set in your inventory.
2. Local variables from the plan.
3. vars set in your inventory.

Like the code compiled with the puppet apply command, all the variables are generated. PE copies custom module content from the module path to the targets and applies the catalog.

After the catalog compiles and is executed successfully on all targets, apply returns the reports generated by applying the catalog on each target.

**Return value**

The apply function returns a ResultSet object that contains an ApplyResult object for each target.

For example:

```puppet
$results = apply($targets) { ... }
$results.each |$result| {
    notice($result.report)
}
```

**Computing complex values**

To compute complex values, you can use a Puppet code expression as the value of any field of a step except the name.

Bolt loads the plan as a YAML data structure. As it executes each step, it evaluates any expressions embedded in the step. Each plan parameter and the values of every previous named step are available in scope.

This lets you take advantage of the power of Puppet language in the places it's necessary, while keeping the rest of your plan simple.

When your plans need more sophisticated control flow or error handling beyond running a list of steps in order, it's time to convert them to Puppet Language plans.
Converting YAML plans to Puppet language plans
You can convert a YAML plan to a Puppet language plan with the `bolt plan convert` command.

```
bolt plan convert path/to/my/plan.yaml
```

This command takes the relative or absolute path to the YAML plan to be converted and prints the converted Puppet language plan to stdout.

**Note:** Converting a YAML plan might result in a Puppet plan which is syntactically correct, but behaves differently. Always manually verify a converted Puppet language plan's functionality. There are some constructs that do not translate from YAML plans to Puppet language plans. These are listed [TODO: insert link to section below!] below. If you convert a YAML plan to Puppet and it changes behavior, file an issue in Bolt’s Git repo.

For example, with this YAML plan:

```yaml
# site-modules/mymodule/plans/yamlplan.yaml
parameters:
  nodes:
    type: TargetSpec
steps:
- name: run_task
  task: sample
  target: $nodes
  parameters:
    message: "hello world"
  return: $run_task
```

Run the following conversion:

```
$ bolt plan convert site-modules/mymodule/plans/yamlplan.yaml
# WARNING: This is an autogenerated plan. It may not behave as expected.
plan mymodule::yamlplan(
  TargetSpec $nodes
)
{
  $run_task = run_task('sample', $nodes, {'message' => "hello world"})
  return $run_task
}
```

Quirks when converting YAML plans to Puppet language
There are some quirks and limitations associated with converting a plan expressed in YAML to a plan expressed in the Puppet language. In some cases it is impossible to accurately translate from YAML to Puppet. In others, code that is generated from the conversion is syntactically correct but not idiomatic Puppet code.

**Named eval step**
The `eval` step allows snippets of Puppet code to be expressed in YAML plans. When converting a multi-line `eval` step to Puppet code and storing the result in a variable, use the `with` lambda.

For example, here is a YAML plan with a multi-line `eval` step:

```yaml
parameters:
  foo:
    type: Optional[Integer]
    description: foo
    default: 0

steps:
- eval: |
  $x = $foo + 1
  $x * 2
  name: eval_step
```
return: $eval_step

And here is the same plan, converted to the Puppet language:

```puppet
plan yaml_plans::with_lambda(
  Optional[Integer] $foo = 0
) {
  $eval_step = with() || {
    $x = $foo + 1
    $x * 2
  }

  return $eval_step
}
```

Writing this plan from scratch using the Puppet language, you would probably not use the lambda. In this example the converted Puppet code is correct, but not as natural or readable as it could be.

**Resource step variable interpolation**

When applying Puppet resources in a resource step, variable interpolation behaves differently in YAML plans and Puppet language plans. To illustrate this difference, consider this YAML plan:

```yaml
steps:
  - target: localhost
description: Apply a file resource
resources:
  - type: file
title: '/tmp/foo'
parameters:
  content: $facts['os']['family']
  ensure: present
- name: file_contents
description: Read contents of file managed with file resource
eval: 
  file::read('/tmp/foo')

return: $file_contents
```

This plan performs `apply_prep` on a localhost target. Then it uses a Puppet `file` resource to write the OS family discovered from the Puppet `$facts` hash to a temporary file. Finally, it reads the value written to the file and returns it. Running `bolt plan convert` on this plan produces this Puppet code:

```puppet
plan yaml_plans::interpolation_pp() { 
  apply_prep('localhost')
  $interpolation = apply('localhost') {
    file {
      '/tmp/foo':
        content => $facts['os']['family'],
        ensure => 'present',
    }
  }
  $file_contents = file::read('/tmp/foo')

  return $file_contents
}
```

This Puppet language plan works as expected, whereas the YAML plan it was converted from fails. The failure stems from the `$facts` variable being resolved as a plan variable, instead of being evaluated as part of compiling the manifest code in an `apply` block.

© 2020 Puppet, Inc.
Dependency order

The resources in a `resources` list are applied in order. It is possible to set dependencies explicitly, but when doing so you must refer to them in a particular way. Consider the following YAML plan:

```yaml
parameters:
  nodes:
    type: TargetSpec
steps:
  - name: pkg
    target: $nodes
    resources:
      - title: openssh-server
        type: package
        parameters:
          ensure: present
          before: File['/etc/ssh/sshd_config']
      - title: /etc/ssh/sshd_config
        type: file
        parameters:
          ensure: file
          mode: '0600'
          content: ''
          require: Package['openssh-server']
```

Executing this plan fails during catalog compilation because of how Bolt parses the resources referenced in the `before` and `require` parameters. You will see the error message `Could not find resource 'File['/etc/ssh/sshd_config']' in parameter 'before'. The solution is to not quote the resource titles:

```yaml
parameters:
  nodes:
    type: TargetSpec
steps:
  - name: pkg
    target: $nodes
    resources:
      - title: openssh-server
        type: package
        parameters:
          ensure: present
          before: File[/etc/ssh/sshd_config]
      - title: /etc/ssh/sshd_config
        type: file
        parameters:
          ensure: file
          mode: '0600'
          content: ''
          require: Package[openssh-server]
```

In general, declare resources in order. This is an unusual example to illustrate a case where parameter parsing leads to non-intuitive results.

Writing plans in Puppet Language

Plans allow you to run more than one task with a single command, compute values for the input to a task, process the results of tasks, or make decisions based on the result of running a task.

Write plans in the Puppet language, giving them a `.pp` extension, and place them in the module's `/plans` directory. Plans can use any combination of Bolt functions or built in Puppet functions.
**Naming plans**

It is important to name plans correctly according to the module name, file name, and path to ensure easy code readability.

Place plan files in your module's `.plans` directory, using these file extensions:

- Puppet plans — `.pp`
- YAML plans — `.yaml`, not `.yml`

Plan names are composed of two or more name segments, indicating:

- The name of the module the plan is located in.
- The name of the plan file, without the extension.
- The path within the module, if the plan is in a subdirectory of `.plans`.

For example, given a module called `mymodule` with a plan defined in `./mymodule/plans/myplan.pp`, the plan name is `mymodule::myplan`.

A plan defined in `./mymodule/plans/service/myplan.pp` would be `mymodule::service::myplan`. This name is how you refer to the plan when you run commands.

The plan filename `init` is special: the plan it defines is referenced using the module name only. For example, in a module called `mymodule`, the plan defined in `init.pp` is the `mymodule` plan.

Avoid giving plans the same names as constructs in the Puppet language. Although plans do not share their namespace with other language constructs, giving plans these names makes your code difficult to read.

Each plan name segment must begin with a lowercase letter and:

- May include lowercase letters.
- May include digits.
- May include underscores.
- Must not be a reserved word.
- Must not have the same name as any Puppet data types.
- Namespace segments must match the following regular expression `\A[a-z][a-z0-9_]*\Z`

**RBAC considerations for writing plans**

Take user permissions into consideration when writing plans by understanding how RBAC for plans works.

RBAC for plans is separate from RBAC for individual tasks. This means that a user can be excluded from running a certain task, but still have permission to run a plan that contains that task. Setting one permission does not affect the other.

This structure allows you to write plans with more robust, custom control over task permissions. Instead of allowing a user free rein to run a task that can potentially damage your infrastructure under the right conditions, you can wrap a task in a plan and only allow them to run it under circumstances you can control.

For example, say you are configuring permissions for a new user and allow them to run the plan `plan infra::upgrade_git`:

```powershell
plan infra::upgrade_git {
    TargetSpec $nodes,
    Integer $version,
} {
    run_task('package', $nodes, name => 'git', action => 'upgrade', version => $version)
}
```

Within this plan, they can run the `package` task, but can only interact with the `git` package. The plan does not allow them to use any other parameters for the `package` task.
Even though they can run this plan, they do not have access to individually run the package task outside of this plan unless you grant them permission to do so. In that case, they would have the option to add any parameters they want to the task.

**Use parameter types to fine-tune access**

Writing parameter types into plan code provides even more control. In the upgrade_git example above, the plan only provides access to the git package, but the user can choose whatever version of git they want.

Let's say there are known vulnerabilities in some versions of the git package and you are concerned with your new user having the ability to use the versions you deem unsafe. You can use parameter types like Enum to restrict the version parameter to versions that are safe enough for deployment.

In this example, the Enum restricts the $version parameter to versions 1:2.17.0-1ubuntu1 and 1:2.17.1-1ubuntu0.4 only:

```plaintext
plan infra::upgrade_git (  
  TargetSpec $nodes,  
  Enum['1:2.17.0-1ubuntu1', '1:2.17.1-1ubuntu0.4'] $version,  
) {  
  run_task('package', $nodes, name => 'git', action => 'upgrade', version => $version)  
}
```

Any user attempting to run this plan must choose one of these versions for the plan to run.

You can also use PuppetDB queries to select parameter types. Using the same example, let's say you need to restrict the nodes that infra::upgrade_git can run on. Use a PuppetDB query to identify which nodes get selected for the git upgrade. It should look something like this:

```plaintext
plan infra::upgrade_git (  
  Enum['1:2.17.0-1ubuntu1', '1:2.17.1-1ubuntu0.4'] $version,  
) {  
  # Use puppetdb to find the nodes from the "other" team's web cluster  
  $query = [from, nodes, ['=', [fact, cluster], "other_team"]]
  $selected_nodes = puppetdb_query($query).map() |$target| {  
    $target[certname]
  }
  run_task('package', $selected_nodes, name => 'git', action => 'upgrade', version => $version)  
}
```

Using these ideas, you can write powerful plans that give users exactly what they need without giving them the keys to the kingdom.

**Plan caveats and limitations**

Some plan language and features are not available in PE or have some caveats.

**Bolt modules are not included**

The following modules that come pre-installed with open source Bolt are not available by default in PE:

- aggregate
- canary
- puppetdb_fact
- ruby_task_helper
- python_task_helper
- facts
  - The PE equivalent of facts is factor_task
• puppet_agent
  • The PE equivalent of puppet_agent is pe_bootstrap

Plan language functions
The following Bolt plan functions will not work in PE and using them will cause a plan to fail:
- file::read
- file::write
- file::readable
- file::exists
- set_feature
- add_to_group
- set_config

Apply blocks
The apply feature, including apply_prep, only works only for targets using the PXP agent and the PCP transport. It will fail on targets connected via SSH or WinRM.

Target groups
Support for target groups is unavailable in PE. Using add_to_group will cause a plan to fail and referencing a group name in get_targets will not return any nodes. When using get_targets you must reference either node certnames or supply a PuppetDB query.

Here is an example of a plan using get targets with node certnames:

```ruby
plan example::get_targets_example () {
  $nodes = get_targets(['node1.example.com', 'node2.example.com'])
  run_command('whoami', $nodes)
}
```

Target features
Support for target features is unavailable in PE. Using set_feature will cause a plan to fail and referencing a target object’s features list will always return an empty array.

Here is an example of a plan that would return an empty features list:

```ruby
plan example::empty_features_example (TargetSpec $node) {
  return get_target($node).features()
}
```

Target configuration
While you can set up node transport configuration through the PE inventory for nodes to use SSH or WinRM, plans in PE do not support setting or changing the configuration settings for targets from within a plan. Using the set_config function in a plan will cause a plan to fail and referencing a target object’s configuration hash will always return an empty hash.

The use of URIs in a target name to override the transport is also not supported. All references to targets (i.e. when using get_targets) must be either PuppetDB queries or valid certnames that are already in the PE inventory.

Here is an example of a plan that uses get_targets correctly:

```ruby
plan example::get_targets_example () {
  ## NOTE! If you used ssh://node1.example.com as the first entry, this plan would fail!
```
$nodes = get_targets(['node1.example.com', 'node2.example.com'])
run_command('whoami', $nodes)
}

_run_as options in plan functions

Plans in PE does not support the _run_as parameter for changing the user that accesses hosts or executes actions. If this parameter is supplied to any plan function, the plan will execute but the user will not change.

For example, the following plan will succeed, but will not run as other_user:

plan example::run_as_example (TargetSpec $nodes) {
  run_command('whoami', $nodes, _run_as => 'other_user')
}

The localhost target

The special target localhost is not available for plans in PE. Using localhost anywhere in a plan will result in a plan failure. If you need to run a plan on the PE master host, use the master's certname to reference it.

For example, you can use the following plan for PE master host my-pe-master.company.com:

plan example::referencing_the_master()
  # Note that if you tried to use `localhost` instead of `my-pe-master` this plan would fail!
  run_command('whoami', 'my-pe-master.company.com')

Standard Puppet log functions

Puppet's built-in logging functions, like notice and warn, will not log anywhere. Plans with those functions will still work, but the logging messages will not appear.

If you need to use a logging function in your plan, the out::message() plan function will write an event to the orchestrator's event stream.

For example, the following will log the message correctly to the event stream:

plan example::logging(){
  out::message("This will output to the orchestrator event stream")
}

This will not log any messages:

plan example::bad_logging(){
  # neither of the following will output any messages anywhere
  notice("this will go nowhere!")
  warn("this will also go nowhere!")
}

Script and file sources

When using run_script or download_file, the source location for the files must be from a module that uses a modulename/filename selector for a file or directory in $MODULEROOT/files. PE does not support file sources that reference absolute paths.

Here is an example of a module structure and a plan that correctly uses the modulename/filename selector:

example/
### files
Code deployment for plans

For plans in PE to work, you must have code manager enabled to deploy code to your master.

Masters will now deploy a second codedir for plans to load code from. The second code location on masters have some effects on standard module functionality:

- Installation modules using the `puppet module install` command will not work for plans because the puppet module tool will not install to the secondary location for plans. The `puppet module install` command will still work for normal Puppet code executed and compiled from Puppet Server.
- A `$modulepath` configuration that uses fully qualified paths might not work for plans if they reference the standard `/etc/puppetlabs/code` location. We recommend using relative paths in `$modulepath`.

Defining plan parameters

Specify parameters within your plan.

Specify each parameter in your plan with its data type. For example, you might want parameters to specify which nodes to run different parts of your plan on.

The following example shows node parameters specified as data type `TargetSpec`. This allows this parameter to be passed as a single URL, comma-separated URL list, Target data type, or Array of either. For more information about these data types, see the common data types table in the related metadata type topic.

This allows the user to pass, for each parameter, either a node name or a URI that describes the protocol to use, the hostname, username, and password.

The plan then calls the `run_task` function, specifying which nodes to run the tasks on. The Target names are collected and stored in `$webserver_names` by iterating over the list of `Target` objects returned by `get_targets`. Task parameters are serialized to JSON format; therefore, extracting the names into an array of strings ensures that the `webservers` parameter is in a format that can be converted to JSON.

```puppet
plan mymodule::my_plan(
    TargetSpec $load_balancer,
    TargetSpec $webservers,
) {
    # Extract the Target name from $webservers
    $webserver_names = get_targets($webservers).map |$n| { $n.name }
    # process webservers
    run_task('mymodule::lb_remove', $load_balancer, webservers => $webserver_names)
    run_task('mymodule::update_frontend_app', $webservers, version => '1.2.3')
    run_task('mymodule::lb_add', $load_balancer, webservers => $webserver_names)
}
```

To execute this plan from the command line, pass the parameters as `parameter=value`. The `TargetSpec` accepts either an array as json or a comma separated string of target names.

```bash
bolt plan run mymodule::myplan --modulepath ./PATH/TO/MODULES
load_balancer=lb.myorg.com
webservers='["kermit.myorg.com","gonzo.myorg.com"]'
```

© 2020 Puppet, Inc.
Parameters that are passed to the `run_*` plan functions are serialized to JSON.

To illustrate this concept, consider this plan:

```bash
plan test::parameter_passing (TargetSpec $nodes,
   Optional[String[1]] $example_nul = undef,
) {
   return run_task('test::demo.Undef_bash', $nodes, example_nul => $example_nul)
}
```

The default value of `$example_nul` is `undef`. The plan calls the `test::demo.Undef_bash` with the `example_nul` parameter. The implementation of the `demo.Undef_bash.sh` task is:

```bash
#!/bin/bash
example_env=$PT_example_nul
echo "Environment: $PT_example_nul"
echo "Stdin:"
cat -
```

By default, the task expects parameters passed as a JSON string on stdin to be accessible in prefixed environment variables.

Consider the output of running the plan against localhost:

```bash
bolt@bolt: bolt plan run test::parameter_passing -n localhost
Starting: plan test::parameter_passing
Starting: task test::demo.Undef_bash on localhost
Finished: task test::demo.Undef_bash with 0 failures in 0.0 sec
Finished: plan test::parameter_passing in 0.01 sec
Finished on localhost:
   Environment: null
   Stdin:
      {"example_nul":null,"_task":"test::demo.Undef_bash"}
   }
Successful on 1 node: localhost
   Ran on 1 node
```

The parameters `example_nul` and `_task` metadata are passed to the task as a JSON string over stdin.

Similarly, parameters are made available to the task as environment variables where the name of the parameter is converted to an environment variable prefixed with `PT_`. The prefixed environment variable points to the `String` representation in JSON format of the parameter value. So, the `PT_example_nul` environment variable has the value of `null` of type `String`.

**Returning results from plans**

Use plans to return results that you can use in other plans or save for use outside of Bolt.

Plans, unlike functions, are primarily run for side effects but they can optionally return a result. To return a result from a plan use the `return` function. Any plan that does not call the `return` function returns `undef`.

```bash
plan return_result($nodes) {
   return run_task('mytask', $nodes)
}
```
The result of a plan must match the `PlanResult` type alias. This roughly includes JSON types as well as the Plan language types which have well defined JSON representations in Bolt.

- Undef
- String
- Numeric
- Boolean
- Target
- Result
- ResultSet
- Error
- Array with only `PlanResult`
- Hash with string keys and `PlanResult` values

or

```ruby
Variant[Data, String, Numeric, Boolean, Error, Result, ResultSet, Target,
Array[Boltlib::PlanResult], Hash[String, Boltlib::PlanResult]]
```

**Returning errors in plans**
To return an error if your plan fails, call the `fail_plan` function.

Specify parameters to provide details about the failure.

For example, if called with `run_plan('mymodule::myplan')`, this would return an error to the caller.

```ruby
plan mymodule::myplan {
  Error(
    message => "Sorry, this plan does not work yet.",
    kind => 'mymodule/error',
    issue_code => 'NOT_IMPLEMENTED'
  )
  fail_plan("Sorry, this plan does not work yet.", 'mymodule/error')
}
```

**Plan success and failure**
There are indicators that a plan has run successfully or failed.

Any plan that completes execution without an error is considered successful. The `bolt` command exits 0 and any calling plans continue execution. If any calls to `run_` functions fail without `_catch_errors` then the plan halts execution and is considered a failure. Any calling plans also halt until a `run_plan` call with `_catch_errors` or a `catch_errors` block is reached. If one isn't reached, the `bolt` command performs an exit 2. When writing a plan if you have reason to believe it has failed, you can fail the plan with the `fail_plan` function. This causes the `bolt` command to exit 2 and prevents calling plans executing any further, unless `run_plan` was called with `_catch_errors` or in a `catch_errors` block.

**Failing plans**
If `upload_file`, `run_command`, `run_script`, or `run_task` are called without the `_catch_errors` option and they fail on any nodes, the plan itself fails. To fail a plan directly call the `fail_plan` function. Create a new error with a message and include the kind, details, or issue code, or pass an existing error to it.

```ruby
fail_plan('The plan is failing', 'mymodules/pear-shaped', {'failednodes' => $result.error_set.names})
# or
fail_plan($errorobject)
```
pe | Orchestrating Puppet, tasks, and plans | 519

Catching errors in plans
Bolt includes a catch_errors function that executes a block of code and returns the error if an error is raised, or
returns the result of the block if no errors are raised. You might get an Error object returned if you call run_plan
with _catch_errors, use a catch_errors block, or call the Error method on a result.
The Error data type includes:
•
•
•
•

msg: The error message string.
kind: A string that defines the kind of error similar to an error class.
details: A hash with details about the error from a task or from information about the state of a plan when it
fails, for example, exit_code or stack_trace.
issue_code: A unique code for the message that can be used for translation.

Use the Error data type in a case expression to match against different kind of errors. To recover from certain
errors, while failing on or ignoring others, set up your plan to include conditionals based on errors that occur while
your plan runs. For example, you can set up a plan to retry a task when a timeout error occurs, but to fail when there
is an authentication error.
Below, the first plan continues whether it succeeds or fails with a mymodule/not-serious error. Other errors
cause the plan to fail.
plan mymodule::handle_errors {
$result = run_plan('mymodule::myplan', '_catch_errors' => true)
case $result {
Error['mymodule/not-serious'] : {
notice("${result.message}")
}
Error : { fail_plan($result) } }
run_plan('mymodule::plan2')
}
Using the catch errors function:
plan test (String[1] $role) {
$result_or_error = catch_errors(['bolt/puppetdb-error']) || {
puppetdb_query("inventory[certname] { app_role == ${role} }")
}
$targets = if $result_or_error =~ Error {
# If the PuppetDB query fails
warning("Could not fetch from puppet. Using defaults instead")
# TargetSpec string
"all"
} else {
$result_or_error
}
}
Puppet and Ruby functions in plans
You can define and call Puppet language and Ruby functions in plans.
This is useful for packaging common general logic in your plan. You can also call the plan functions, such as
run_task or run_plan, from within a function.
Not all Puppet language constructs are allowed in plans. The following constructs are not allowed:
•
•
•
•
•

Defined types.
Classes.
Resource expressions, such as file { title: mode => '0777' }
Resource default expressions, such as File { mode => '0666' }
Resource overrides, such as File['/tmp/foo'] { mode => '0444' }

© 2020 Puppet, Inc.


- Relationship operators: \( \rightarrow \), \( \leftarrow \), \( \leftrightarrow \)
- Functions that operate on a catalog: include, require, contain, create_resources.
- Collector expressions, such as SomeType \( <| |> \), SomeType \( <<| |>> \)
- ERB templates are not supported. Use EPP instead.

Be aware of a few other Puppet behaviors in plans:
- The \(--\text{strict\_variables}\) option is on, so if you reference a variable that is not set, you get an error.
- \(--\text{strict\_error}\) is always on, so minor language issues generate errors. For example \{ a => 10, a => 20 \} is an error because there is a duplicate key in the hash.
- Most Puppet settings are empty and not-configurable when using Bolt.
- Logs include "source location" (file, line) instead of resource type or name.

**Handling plan function results**

Each execution function returns an object type ResultSet. For each node that the execution takes place on, this object contains a Result object. The apply action returns a ResultSet containing ApplyResult objects.

A ResultSet has the following methods:
- names(): The String names (node URIs) of all nodes in the set as an Array.
- empty(): Returns Boolean if the execution result set is empty.
- count(): Returns an Integer count of nodes.
- first(): The first Result object, useful to unwrap single results.
- find(String $target_name): Look up the Result for a specific target.
- error_set(): A ResultSet containing only the results of failed nodes.
- ok_set(): A ResultSet containing only the successful results.
- filter_set(block): Filters a ResultSet with the given block and returns a ResultSet object (where the filter function returns an array or hash).
- targets(): An array of all the Target objects from every Result in the set.
- ok(): Boolean that is the same as error_set.empty.
- to_data(): An array of hashes representing either Result or ApplyResults.

A Result has the following methods:
- value(): The hash containing the value of the Result.
- target(): The Target object that the Result is from.
- error(): An Error object constructed from the _error in the value.
- message(): The _output key from the value.
- ok(): Returns true if the Result was successful.
- []: Accesses the value hash directly.
- to_data(): Hash representation of Result.
- action(): String representation of result type (task, command, etc.).

An ApplyResult has the following methods:
- report(): The hash containing the Puppet report from the application.
- target(): The Target object that the Result is from.
- error(): An Error object constructed from the _error in the value.
- ok(): Returns true if the Result was successful.
- to_data(): Hash representation of ApplyResult.
- action(): String representation of result type (apply).

An instance of ResultSet is Iterable as if it were an Array[Variant[Result, ApplyResult]] so that iterative functions such as each, map, reduce, or filter work directly on the ResultSet returning each result.
This example checks if a task ran correctly on all nodes. If it did not, the check fails:

```puppet
$r = run_task('sometask', ..., '_catch_errors' => true)
unless $r.ok {
  fail("Running sometask failed on the nodes ${r.error_set.names}")
}
```

You can do iteration and checking if the result is an Error. This example outputs feedback about the result of a task:

```puppet
$r = run_task('sometask', ..., '_catch_errors' => true)
$r.each |$result| {
  $node = $result.target.name
  if $result.ok {
    notice("${node} returned a value: ${result.value}")
  } else {
    notice("${node} errored with a message: ${result.error.message}")
  }
}
```

Similarly, you can iterate over the array of hashes returned by calling `to_data` on a `ResultSet` and access hash values. For example:

```puppet
$r = run_command('whoami', 'localhost,local://0.0.0.0')
$r.to_data.each |$result_hash| { notice($result_hash['result']['stdout']) }
```

You can also use `filter_set` to filter a `ResultSet` and apply a `ResultSet` function such as `targets` to the output:

```puppet
$filtered = $result.filter_set |$r| {
  $r['tag'] == "you're it"
}.targets
```

### Passing sensitive data to tasks

Task parameters defined as sensitive are masked when they appear in plans.

You define a task parameter as sensitive with the metadata property "sensitive": true. When a task runs, the values for these sensitive parameters are masked.

```puppet
run_task('task_with_secrets', ..., password => '$ecret!')
```

### Working with the sensitive function

In Puppet you use the Sensitive function to mask data in output logs. Because plans are written in Puppet DSL, you can use this type freely. The `run_task()` function does not allow parameters of `Sensitive` function to be passed. When you need to pass a sensitive value to a task, you must unwrap it prior to calling `run_task()`.

```puppet
$pass = Sensitive('$ecret!')
run_task('task_with_secrets', ..., password => $pass.unwrap)
```

### Target objects

The Target object represents a node and its specific connection options.

The state of a target is stored in the inventory for the duration of a plan allowing you to collect facts or set vars for a target and retrieve them later. You can get a printable representation via the `name` function, as well as access components of the target: `protocol, host, port, user, password.`
**TargetSpec**

The execution function takes a parameter with the type alias TargetSpec. This alias accepts the pattern strings allowed by `--nodes`, a single Target object, or an Array of Targets and node patterns. Generally, use this type for plans that accept a set of targets as a parameter, to ensure clean interaction with the CLI and other plans. To operate on individual nodes, resolve it to a list via `get_targets`. For example, to loop over each node in a plan accept a TargetSpec argument, but call `get_targets` on it before looping.

```ruby
plan loop(TargetSpec $nodes) {
  get_targets($nodes).each |$target| {
    run_task('my_task', $target)
  }
}
```

If your plan accepts a single TargetSpec parameter you can call that parameter `nodes` so that it can be specified with the `--nodes` flag from the command line.

**Variables and facts on targets**

When Bolt runs, it loads transport config values, variables, and facts from the inventory. These can be accessed with the `target.facts()` and `target.vars()` functions. During the course of a plan, you can update the facts or variables for any target. Facts usually come from running `facter` or another fact collection application on the target or from a fact store like PuppetDB. Variables are computed externally or assigned directly.

Set variables in a plan using `target.set_var`:

```ruby
plan vars(String $host) {
  $target = get_targets($host)[0]
  $target.set_var('newly_provisioned', true)
  $targetvars = $target.vars
  run_command("echo 'Vars for ${host}: ${$targetvars}'", $host)
}
```

Or set variables in the inventory file using the `vars` key at the group level.

```ruby
groups:
  - name: my_nodes
    nodes:
      - localhost
    vars:
      operating_system: windows
      config:
        transport: ssh
```

**Collect facts from the targets**

The facts plan connects to the target and discovers facts. It then stores these facts on the targets in the inventory for later use.

The methods used to collect facts:

- On `ssh` targets, it runs a Bash script.
- On `winrm` targets, it runs a PowerShell script.
- On `pcp` or targets where the Puppet agent is present, it runs Facter.

This example collects facts with the facts plan and then uses those facts to decide which task to run on the targets.

```ruby
plan run_with_facts(TargetSpec $nodes) {
  # This collects facts on nodes and update the inventory
  run_plan(facts, nodes => $nodes)
}
$centos_nodes = get_targets($nodes).filter |$n| { $n.facts['os']['name'] == 'CentOS' }
$ubuntu_nodes = get_targets($nodes).filter |$n| { $n.facts['os']['name'] == 'Ubuntu' }
run_task(centos_task, $centos_nodes)
run_task(ubuntu_task, $ubuntu_nodes)

Collect facts from PuppetDB

When targets are running a Puppet agent and sending facts to PuppetDB, you can use the puppetdb_fact plan to collect facts for them. This example collects facts with the puppetdb_fact plan, and then uses those facts to decide which task to run on the targets. You must configure the PuppetDB client before you run it.

plan run_with_facts(TargetSpec $nodes) {
    # This collects facts on nodes and update the inventory
    run_plan(puppetdb_fact, nodes => $nodes)
    $centos_nodes = get_targets($nodes).filter |$n| { $n.facts['os']['name'] == 'CentOS' }
    $ubuntu_nodes = get_targets($nodes).filter |$n| { $n.facts['os']['name'] == 'Ubuntu' }
    run_task(centos_task, $centos_nodes)
    run_task(ubuntu_task, $ubuntu_nodes)
}

Collect general data from PuppetDB

You can use the puppetdb_query function in plans to make direct queries to PuppetDB. For example you can discover nodes from PuppetDB and then run tasks on them. You'll have to configure the PuppetDB client before running it. You can learn how to structure pql queries here, and find pql reference and examples here.

plan pdb_discover {
    $result = puppetdb_query("inventory[certname] { app_role == 'web_server' }")
    # extract the certnames into an array
    $names = $result.map |$r| { $r["certname"] } 
    # wrap in url. You can skip this if the default transport is pcp
    $nodes = $names.map |$n| { "pcp://${n}" } 
    run_task('my_task', $nodes)
}

Applying manifest blocks from a plan

You can apply manifest blocks to remote systems during plan execution using the apply and apply_prep functions.

Manifest blocks require facts to compile. If your plan includes a manifest block, use the apply_prep function in your plan before your manifest block. The apply_prep function syncs and caches plugins and gathers facts by running facter, making the facts available to the manifest block.

For example:

apply_prep($target)
apply($target) { notify { foo: } }

Note: You can only use apply and apply_prep on nodes connected via PCP.

apply options

The apply function supports the following options.
<table>
<thead>
<tr>
<th>Option</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>_catch_errors</code></td>
<td>true</td>
<td>Returns a ResultSet, including failed results, rather than failing the plan.</td>
</tr>
<tr>
<td><code>_description</code></td>
<td>none</td>
<td>Adds a description to the apply block.</td>
</tr>
<tr>
<td><code>_noop</code></td>
<td>true</td>
<td>Applies the manifest block in no-operation mode, returning a report of changes it would make but does not take action.</td>
</tr>
</tbody>
</table>

For example:

```
# Preview installing docker as root on $targets.
apply($targets, _catch_errors => true, _noop => true) {
  include 'docker'
}
```

**How manifest blocks are applied**

PE compiles the code in your manifest block into a catalog in this order.

1. Facts gathered from the targets set in your inventory.
2. Local variables from the plan.
3. vars set in your inventory.

Like the code compiled with the puppet apply command, all the variables are generated. PE copies custom module content from the module path to the targets and applies the catalog.

After the catalog compiles and is executed successfully on all targets, apply returns the reports generated by applying the catalog on each target.

**Return value**

The apply function returns a ResultSet object that contains an ApplyResult object for each target.

For example:

```
$results = apply($targets) { ... }
$results.each |$result| {
  notice($result.report)
}
```

**Plan logging**

Plan run information can be captured in log files or printed to a terminal session using the following methods.

**Outputting section to the terminal**

Print message strings to STDOUT using the plan function `out::message`. This function always prints messages regardless of the log level and doesn’t log them to the log file.

**Puppet log functions**

To generate log messages from a plan, use the Puppet log function that corresponds to the level you want to track: `error, warn, notice, info, or debug`. Configure the log level for both log files and console logging in `bolt.yaml`. The default log level for the console is `warn` and for log files is `notice`. Use the `--debug` flag to set the console log level to `debug` for a single run.
Default action logging

Bolt logs actions that a plan takes on targets through the `upload_file`, `run_command`, `run_script`, or `run_task` functions. By default it logs a notice level message when an action starts and another when it completes. If you pass a description to the function, that is used in place of the generic log message.

```puppet
run_task(my_task, $targets, "Better description", param1 => "val")
```

If your plan contains many small actions you may want to suppress these messages and use explicit calls to the Puppet log functions instead. This can be accomplished by wrapping actions in a `without_default_logging` block which causes the action messages to be logged at info level instead of notice. For example to loop over a series of nodes without logging each action.

```puppet
plan deploy( TargetSpec $nodes) {
  without_default_logging() || {
    get_targets($nodes).each |$node| {
      run_task(deploy, $node)
    }
  }
}
```

To avoid complications with parser ambiguity, always call `without_default_logging` with () and empty block args `||`.

```puppet
without_default_logging() || { run_command('echo hi', $nodes) }
```

not

```puppet
without_default_logging { run_command('echo hi', $nodes) }
```

Example plans

Check out some example plans for inspiration writing your own.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Description</th>
<th>Level</th>

</tbody>
</table>

- **Getting started** resources show simple use cases such as running a task and manipulating the results.
- **Intermediate** resources show more advanced features in the plan language.
• Advanced resources show more complex use cases such as applying puppet code blocks and using external modules.

Puppet orchestrator API v1 endpoints

Use this API to gather details about the orchestrator jobs you run.

• Puppet orchestrator API: forming requests on page 526
Instructions on interacting with this API.
• Puppet orchestrator API: command endpoint on page 528
Use the /command endpoint to start and stop orchestrator jobs for tasks and plans.
• Puppet orchestrator API: events endpoint on page 538
Use the /events endpoint to learn about events that occurred during an orchestrator job.
• Puppet orchestrator API: inventory endpoint on page 544
Use the /inventory endpoint to discover which nodes can be reached by the orchestrator.
• Puppet orchestrator API: jobs endpoint on page 546
Use the /jobs endpoint to examine orchestrator jobs and their details.
• Puppet orchestrator API: scheduled jobs endpoint on page 555
Use the /scheduled_jobs endpoint to gather information about orchestrator jobs scheduled to run.
• Puppet orchestrator API: plans endpoint on page 558
Use the /plans endpoint to see all known plans in your environments.
• Puppet orchestrator API: plan jobs endpoint on page 560
Use the /plan_jobs endpoint to view details about plan jobs you have run.
• Puppet orchestrator API: tasks endpoint on page 565
Use the /tasks endpoint to view details about the tasks pre-installed by PE and those you've installed.
• Puppet orchestrator API: root endpoint on page 569
Use the /orchestrator endpoint to return metadata about the orchestrator API.
• Puppet orchestrator API: usage endpoint on page 570
Use the /usage endpoint to view details about the active nodes in your deployment.
• Puppet orchestrator API: scopes endpoint on page 571
Use the scopes endpoint to retrieve resources for task constraints.
• Puppet orchestrator API: error responses on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

Related information
API index on page 33
APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

Puppet orchestrator API: forming requests
Instructions on interacting with this API.

By default, the orchestrator service listens on port 8143, and all endpoints are relative to the /orchestrator/v1 path. So, for example, the full URL for the jobs endpoint on localhost would be https://localhost:8143/orchestrator/v1/jobs.

Tip: The orchestrator API accepts well-formed HTTP(S) requests.

Authenticating to the orchestrator API with a token
You need to authenticate requests to the orchestrators’s API. You can do this using user authentication tokens.

For detailed information about authentication tokens, see Token-based authentication on page 208. The following example shows how to use a token in an API request.
To use the `jobs` endpoint of the orchestrator API to get a list of all jobs that exist in the orchestrator, along with their associated metadata, you'd first generate a token with the puppet-access tool. You'd then copy that token and replace `<TOKEN>` with that string in the following request:

**Bash**

```bash
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8143/orchestrator/v1/jobs"
curl --insecure --header "$auth_header" "$uri"
```

**Example token usage: deploy an environment**

If you want to deploy an environment with the orchestrator's API, you can form a request with the token you generated earlier. For example:

**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8143/orchestrator/v1/command/deploy"
data='{"environment": "production", "scope" : { "node_group" : "00000000-0000-4000-8000-000000000000" }}',
curl --insecure --header "$type_header" --header "$auth_header" --request POST "$uri" --data "$data"
```

This returns a JSON structure that includes a link to the new job started by the orchestrator.

```json
{
"job" : {
  "id" : "https://orchestrator.vm:8143/orchestrator/v1/jobs/81",
  "name" : "81"
}
}
```

You can make an additional request to get more information about the job. For example:

**Bash**

```bash
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8143/orchestrator/v1/jobs/81"
curl --insecure --header "$auth_header" "$uri"
```

**Related information**

[Token-based authentication](#) on page 208
Authentication tokens allow a user to enter their credentials once, then receive an alphanumeric "token" to use to access different services or parts of the system infrastructure. Authentication tokens are tied to the permissions granted to the user through RBAC, and provide the user with the appropriate access to HTTP requests.

**Puppet orchestrator API: command endpoint**

Use the `/command` endpoint to start and stop orchestrator jobs for tasks and plans.

**POST /command/deploy**

Run the orchestrator across all nodes in an environment.

**Request format**

The request body must be a JSON object using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>The environment to deploy. <strong>This key is required.</strong></td>
</tr>
<tr>
<td>scope</td>
<td>Object, required unless <code>target</code> is specified. The PuppetDB query, a list of nodes, a classifier node group id, or an application/application instance to deploy.</td>
</tr>
<tr>
<td>description</td>
<td>String, a description of the job.</td>
</tr>
<tr>
<td>noop</td>
<td>Boolean, whether to run the agent in no-op mode. The default is <code>false</code>.</td>
</tr>
<tr>
<td>no_noop</td>
<td>Boolean, whether to run the agent in enforcement mode. Defaults to <code>false</code>. This flag overrides <code>noop = true</code> if set in the agent's <code>puppet.conf</code>, and cannot be set to <code>true</code> at the same time as the <code>noop</code> flag.</td>
</tr>
<tr>
<td>concurrency</td>
<td>Integer, the maximum number of nodes to run at one time. The default, if unspecified, is unlimited.</td>
</tr>
<tr>
<td>enforce_environment</td>
<td>Boolean, whether to force agents to run in the same environment in which their assigned applications are defined. This key is required to be <code>false</code> if <code>environment</code> is an empty string</td>
</tr>
<tr>
<td>debug</td>
<td>Boolean, whether to use the <code>--debug</code> flag on Puppet agent runs.</td>
</tr>
<tr>
<td>trace</td>
<td>Boolean, whether to use the <code>--trace</code> flag on Puppet agent runs.</td>
</tr>
<tr>
<td>evaltrace</td>
<td>Boolean, whether to use the <code>--evaltrace</code> flag on Puppet agent runs.</td>
</tr>
<tr>
<td>filetimeout</td>
<td>Integer, sets the <code>--filetimeout</code> flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>http_connect_timeout</td>
<td>Integer, sets the <code>--http_connect_timeout</code> flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>http_keepalive_timeout</td>
<td>Integer, sets the <code>--http_keepalive_timeout</code> flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>http_read_timeout</td>
<td>Integer, sets the <code>--http_read_timeout</code> flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>ordering</td>
<td>String, sets the <code>--ordering</code> flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>skip_tags</td>
<td>String, sets the --skip_tags flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>tags</td>
<td>String, sets the --tags flag on Puppet agent runs to the provided value.</td>
</tr>
<tr>
<td>use_cached_catalog</td>
<td>Boolean, whether to use the --use_cached_catalog flag on Puppet agent runs.</td>
</tr>
<tr>
<td>use_cache_on_failure</td>
<td>Boolean, whether to use the --use_cache_on_failure flag on Puppet agent runs.</td>
</tr>
<tr>
<td>target</td>
<td>String, required unless scope is specified. The name of an application or application instance to deploy. If an application is specified, all instances of that application are deployed. If this key is left blank or unspecified without a scope, the entire environment is deployed. This key is deprecated.</td>
</tr>
</tbody>
</table>

For example, to deploy the node1.example.com environment in no-op mode, the following request is valid:

```json
{
    "environment" : "",
    "noop" : true,
    "scope" : {
        "nodes" : ["node1.example.com"]
    }
}
```

**Scope**

Scope is a JSON object containing exactly one of these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>application</td>
<td>The name of an application or application instance to deploy. If an application type is specified, all instances of that application are deployed.</td>
</tr>
<tr>
<td>nodes</td>
<td>A list of node names to target.</td>
</tr>
<tr>
<td>query</td>
<td>A PuppetDB or PQL query to use to discover nodes. The target is built from certname values collected at the top level of the query.</td>
</tr>
<tr>
<td>node_group</td>
<td>A classifier node group ID. The ID must correspond to a node group that has defined rules. It is not sufficient for parent groups of the node group in question to define rules. The user must also have permissions to view the node group.</td>
</tr>
</tbody>
</table>

To deploy an application instance in the production environment:

```json
{
    "environment" : "production",
    "scope" : {
        "application" : "Wordpress_app[demo]"
    }
}
```
To deploy a list of nodes:

```json
{
    "environment" : "production",
    "scope" : {
        "nodes" : ["node1.example.com", "node2.example.com"]
    }
}
```

To deploy a list of nodes with the `certname` value matching a regex:

```json
{
    "environment" : "production",
    "scope" : {
        "query" : ["from", "nodes", ["~", "certname", ".*"]]
    }
}
```

To deploy to the nodes defined by the "All Nodes" node group:

```json
{
    "environment" : "production",
    "scope" : {
        "node_group" : "00000000-0000-4000-8000-000000000000"
    }
}
```

**Response format**

If all node runs succeed, and the environment is successfully deployed, the server returns a 202 response.

The response is a JSON object containing a link to retrieve information about the status of the job and uses any one of these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL that links to the newly created job.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the newly created job.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "job" : {
        "id" : "https://orchestrator.example.com:8143/orchestrator/v1/jobs/1234"
        "name" : "1234"
    }
}
```

**Error responses**

For this endpoint, the `kind` key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/unknown-environment</td>
<td>If the environment does not exist, the server returns a 404 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/empty-environment</td>
<td>If the environment requested contains no applications or no nodes, the server returns a 400 response.</td>
</tr>
</tbody>
</table>
Key | Definition
---|---
puppetlabs.orchestrator/empty-target | If the application instance specified to deploy does not exist or is empty, the server returns a 400 response.
puppetlabs.orchestrator/dependency-cycle | If the application code contains a cycle, the server returns a 400 response.
puppetlabs.orchestrator/puppetdb-error | If the orchestrator is unable to make a query to PuppetDB, the server returns a 400 response.
puppetlabs.orchestrator/query-error | If a user does not have appropriate permissions to run a query, or if the query is invalid, the server returns a 400 response.

### Related information

**Puppet orchestrator API: forming requests** on page 526
Instructions on interacting with this API.

**Puppet orchestrator API: error responses** on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**POST /command/stop**
Stop an orchestrator job that is currently in progress. Puppet agent runs that are in progress finish, but no new agent runs start. While agents are finishing, the server continues to produce events for the job.

The job transitions to status **stopped** when all pending agent runs have finished.

This command is **idempotent**: it can be issued against the same job any number of times.

### Request format

The JSON body of the request must contain the ID of the job to stop. The job ID is the same value as the `name` property returned with the `deploy` command.

- **job**: the name of the job to stop.

For example:

```json
{
    "job": "1234"
}
```

### Response format

If the job is stopped successfully, the server returns a 202 response. The response uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL that links to the newly created job.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the newly created job.</td>
</tr>
<tr>
<td>nodes</td>
<td>A hash that shows all of the possible node statuses, and how many nodes are currently in that status.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "job" : {
```
Error responses

For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If a job name is not valid, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/unknown-job</td>
<td>If a job name is unknown, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

POST /command/task

Run a permitted task job across a set of nodes.

Request format

The request body must be a JSON object and uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>The environment to load the task from. The default is production.</td>
</tr>
<tr>
<td>scope</td>
<td>The PuppetDB query, list of nodes, or a node group ID. Application scopes are not allowed for task jobs. This key is required.</td>
</tr>
<tr>
<td>description</td>
<td>A description of the job.</td>
</tr>
<tr>
<td>noop</td>
<td>Whether to run the job in no-op mode. The default is false.</td>
</tr>
<tr>
<td>task</td>
<td>The task to run on the targets. This key is required.</td>
</tr>
<tr>
<td>params</td>
<td>The parameters to pass to the task. This key is required, but can be an empty object.</td>
</tr>
</tbody>
</table>

For example, to run the package task on node1.example.com, the following request is valid:

```json
{
    "environment" : "test-env-1",
    "task" : "package",
    "scope" : "node1.example.com",
    "params" : {}
}
```
"params": {
  "action": "install",
  "name": "httpd"
},
"scope": {
  "nodes": ["node1.example.com"]
}

Scope

Scope is a JSON object containing exactly one of the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodes</td>
<td>An array of node names to target.</td>
</tr>
<tr>
<td>query</td>
<td>A PuppetDB or PQL query to use to discover nodes. The target is built from the <code>certname</code> values collected at the top level of the query.</td>
</tr>
<tr>
<td>node_group</td>
<td>A classifier node group ID. The ID must correspond to a node group that has defined rules. It is not sufficient for parent groups of the node group in question to define rules. The user must also have permissions to view the node group. Any nodes specified in the scope that the user does not have permissions to run the task on are excluded.</td>
</tr>
</tbody>
</table>

To deploy an application instance in the production environment, the following request is valid:

```json
{
  "environment": "production",
  "scope": {
    "application": "Wordpress_app[demo]"
  }
}
```

To run a task on a list of nodes, the following request is valid:

```json
{
  "environment": "production",
  "scope": {
    "nodes": ["node1.example.com", "node2.example.com"]
  }
}
```

To run a task on a list of nodes with the `certname` value matching a regex, the following request is valid:

```json
{
  "environment": "production",
  "scope": {
    "query": ["from", "nodes", ["~", "certname", ".*"]]
  }
}
```

To deploy to the nodes defined by the "All Nodes" node group the following request is valid:

```json
{
  "environment": "production",
  "scope": {
```

© 2020 Puppet, Inc.
"node_group" : "00000000-0000-4000-8000-000000000000"
}

Response format
If the task is starts successfully, the response will have a 202 status.
The response will be a JSON object containing a link to retrieve information about the status of the job. The keys of this object are:
• id: an absolute URL that links to the newly created job.
• name: the name of the newly created job. For example:

```json
{
  "job" : { 
    "id" : "https://orchestrator.example.com:8143/orchestrator/v1/jobs/1234",
    "name" : "1234"
  }
}
```

Error responses

</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/unknown-environment</td>
<td>If the environment does not exist, the server returns a 404 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/empty-target</td>
<td>If the application instance specified to deploy does not exist or is empty, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/puppetdb-error</td>
<td>If the orchestrator is unable to make a query to PuppetDB, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/query-error</td>
<td>If a user does not have appropriate permissions to run a query, or if the query is invalid, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/not-permitted</td>
<td>This error occurs when a user does not have permission to run the task on the requested nodes. Server returns a 403 response.</td>
</tr>
</tbody>
</table>

Related information
Puppet orchestrator API: error responses on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

POST /command/task_target
Create a new task-target, which is a collection of tasks, nodes and node groups that define a permission group. When a user has permissions to run via a given task-target, they are granted permissions to run the given set of tasks, on the set of nodes described by the task-target

Request format
The request body must be a JSON object and uses the following keys:
<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>display_name</td>
<td>A required string that is used to name the task-target. No uniqueness requirements</td>
</tr>
<tr>
<td>tasks</td>
<td>An optional array of tasks that correspond to the task-target. There is no requirement that the tasks correspond to existing tasks. If omitted or empty, all_tasks must be provided and set to true.</td>
</tr>
<tr>
<td>all_tasks</td>
<td>An optional boolean to determine if all tasks can be run on designated targets. Defaults to false. If omitted, tasks are required to be specified. If both all_tasks is true and valid tasks are supplied, tasks are ignored and all_tasks is set.</td>
</tr>
<tr>
<td>nodes</td>
<td>An array of certnames that can correspond to both agent and agentless nodes. The user can run the task against the specified nodes. There is no requirement that the nodes correspond to currently available nodes. The array can be empty.</td>
</tr>
<tr>
<td>node_groups</td>
<td>An array of node-group-ids that describe the set of nodes the task can be run against. The possible nodes described by the node group will be combined with any nodes in the <code>nodes</code> array. The array can be empty.</td>
</tr>
<tr>
<td>pql_query</td>
<td>An optional string that is a single PQL query to fetch nodes that the task-target corresponds to. The query results must contain the certnames key in the results to identify the permitted nodes.</td>
</tr>
</tbody>
</table>

For example:

```json
{
  "display_name": "foo",
  "tasks": ["abc", "def"],
  "nodes": ["node1" "node2"],
  "node_groups": ["00000000-0000-4000-8000-000000000000"]
}
```

```json
{
  "display_name": "foo",
  "all_tasks": "true",
  "nodes": ["node1" "node2"],
  "node_groups": ["00000000-0000-4000-8000-000000000000"]
}
```

**Response format**

If the task-target is successfully created, the server will return a 200 response with a JSON object containing a link to retrieve information about the task-target. The keys of this object are:

- **id**: an absolute URL to retrieve the individual task-target.
- **name**: a unique identifier for the task-target.

For example:

```json
{
  "task_target": {
    "id": "https://orchestrator.example.com:8143/orchestrator/v1/scopes/task_targets/1",
    "name": "1"
  }
}
```
Error responses

For this endpoint, the kind key of the error displays the conflict. See the Puppet orchestrator API: error responses on page 574 documentation for the general format of error responses.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If there is no display name supplied, there are no tasks specified when supplied, task names are not strings, all_tasks is not a boolean when supplied, all_tasks is not set to true when tasks are not supplied, node names are not strings, node-group ids are not strings, or pql_query is not a string the service returns a 400 response.</td>
</tr>
</tbody>
</table>

POST /command/schedule_task

Schedule a task to run at a future date and time.

Request format

The request body must be a JSON object and uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>task</td>
<td>The task to run on the targets. Required.</td>
</tr>
<tr>
<td>params</td>
<td>The parameters to pass to the task. Required.</td>
</tr>
<tr>
<td>scope</td>
<td>The PuppetDB query, list of nodes, or a node group ID. Application scopes are not allowed for task jobs. Required.</td>
</tr>
<tr>
<td>scheduled_time</td>
<td>The ISO-8601 timestamp the determines when to run the scheduled job. If timestamp is in the past, a 400 error is thrown. Required.</td>
</tr>
<tr>
<td>description</td>
<td>A description of the job.</td>
</tr>
<tr>
<td>environment</td>
<td>The environment to load the task from. The default is production.</td>
</tr>
<tr>
<td>noop</td>
<td>Whether to run the job in no-op mode. The default is false.</td>
</tr>
</tbody>
</table>

For example, to run the package task on node1.example.com, the following request is valid:

```json
{
    "environment" : "test-env-1",
    "task" : "package",
    "params" : {
        "action" : "install",
        "package" : "httpd"
    },
    "scope" : {
        "nodes" : ["node1.example.com"]
    },
    "scheduled_time" : "2027-05-05T19:50:08Z"
}
```

Response format

If the task schedules successfully the server returns 202.
The response is a JSON object containing a link to retrieve information about the status of the job. The following keys are available.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL that links to the newly created job.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the newly created job.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "scheduled_job" : {
        "id" : "https://orchestrator.example.com:8143/orchestrator/v1/scheduled_jobs/2",
        "name" : "1234"
    }
}
```

**Error responses**

For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/invalid-time</td>
<td>If the scheduled_time provided is in the past, the server returns a 400 response.</td>
</tr>
</tbody>
</table>

**Related information**

Puppet orchestrator API: error responses on page 574

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**POST /command/plan_run**

Run a plan via the plan executor.

**Request format**

The request body must be a JSON object. The following keys are available:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan_name</td>
<td>String, the name of the plan to run.</td>
</tr>
<tr>
<td>params</td>
<td>Hash, the parameters the job will use.</td>
</tr>
<tr>
<td>environment</td>
<td>String, environment to load the plan from. The default is production.</td>
</tr>
<tr>
<td>description</td>
<td>String, description of the job.</td>
</tr>
</tbody>
</table>

To start the canary plan, the following request is valid:

```json
{
    "plan_name" : "canary",
    "description" : "Start the canary plan on node1 and node2",
    "params" : {
        "nodes" : ["node1.example.com", "node2.example.com"],
        "command" : "whoami",
        "canary" : 1
    }
}
```
Response format
If the plan starts successfully, the response will have status 202.
The response will be a JSON object containing the generated plan job name.
For example:

```json
{
    "name" : "1234"
}
```

Error responses
See the error response documentation for the general format of error response. For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the plan name is not valid the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/not-permitted</td>
<td>This error occurs if a user makes a request they lack permissions for. The server returns a 403 response.</td>
</tr>
</tbody>
</table>

Puppet orchestrator API: events endpoint
Use the /events endpoint to learn about events that occurred during an orchestrator job.

GET /jobs/:job-id/events
Retrieve all of the events that occurred during a given job.

Parameters
The request accepts this query parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>Start the list of events with the nth event.</td>
</tr>
</tbody>
</table>

For example:

```
https://orchestrator.example.com:8143/orchestrator/v1/jobs/352/events?
  start=1272
```

Response format
The response is a JSON object that details the events in a job, and uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>next-events</td>
<td>A link to the next event in the job.</td>
</tr>
<tr>
<td>items</td>
<td>A list of all events related to the job.</td>
</tr>
<tr>
<td>id</td>
<td>The job ID.</td>
</tr>
<tr>
<td>type</td>
<td>The current status of the event. See event-types.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the event was created.</td>
</tr>
</tbody>
</table>
For example:

```json
{
    "next-events": {
        "id": "https://orchestrator.example.com:8143/orchestrator/v1/jobs/352/events?start=1272"
    },
    "items": [
        {
            "id": "1267",
            "type": "node_running",
            "timestamp": "2016-05-05T19:50:08Z",
            "details": {
                "node": "puppet-agent.example.com",
                "detail": {
                    "noop": false
                }
            },
            "message": "Started puppet run on puppet-agent.example.com ..."
        }
    ]
}
```

### Event types

The response format for each event contains one of these event types, which is determined by the status of the event.

<table>
<thead>
<tr>
<th>Event type</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_errored</td>
<td>Created when there was an error running Puppet on a node.</td>
</tr>
<tr>
<td>node_failed</td>
<td>Created when Puppet failed to run on a node.</td>
</tr>
<tr>
<td>node_finished</td>
<td>Created when puppet ran successfully on a node.</td>
</tr>
<tr>
<td>node_running</td>
<td>Created when Puppet starts running on a node.</td>
</tr>
<tr>
<td>node_skipped</td>
<td>Created when a Puppet run is skipped on a node (for example, if a dependency fails).</td>
</tr>
<tr>
<td>job_aborted</td>
<td>Created when a job is aborted without completing.</td>
</tr>
<tr>
<td>job_stopping</td>
<td>Created when a stop request is received and the job is running.</td>
</tr>
<tr>
<td>job_finished</td>
<td>Created when a job is no longer running. The details contain final state. This should always be the last event for a job.</td>
</tr>
</tbody>
</table>

### Error responses

For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the start parameter or the job-id in the request are not integers, the server returns a 400 response.</td>
</tr>
</tbody>
</table>
Key | Definition
--- | ---
puppetlabs.orchestrator/unknown-job | If the job does not exist, the server returns a 404 response.

**Related information**
*Puppet orchestrator API: error responses* on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**GET /plan_jobs/:job-id/events**
Retrieve all of the events that occurred during a given plan job.

**Parameters**
The request accepts the following query parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>The lowest database ID of an event that should be shown.</td>
</tr>
</tbody>
</table>

For example:

https://orchestrator.example.com:8143/orchestrator/v1/plan_jobs/352/events?start=1272

**Response format**
The response is a JSON object that derails the events in a plan job. The following keys and their subkeys are used:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>next-events</td>
<td>A link to the next event in the job.</td>
</tr>
<tr>
<td>• id</td>
<td>The url of the next event.</td>
</tr>
<tr>
<td>• event</td>
<td>The next event id.</td>
</tr>
<tr>
<td>items</td>
<td>A list of all events related to the job.</td>
</tr>
<tr>
<td>• id</td>
<td>The id of the event.</td>
</tr>
<tr>
<td>• type</td>
<td>The type of event. See event-types.</td>
</tr>
<tr>
<td>• timestamp</td>
<td>The time when the event was created.</td>
</tr>
<tr>
<td>• details</td>
<td>Details of the event, differs based on the type of the event. See the potential values section for more detailed information.</td>
</tr>
</tbody>
</table>

For example:

```json
{
  "next-events" : {
    "id" : "https://orchestrator.example.com:8143/orchestrator/v1/plan_jobs/352/events?start=1272",
    "event" : "1272"
  },
  "items" : [ {
    "id" : "1267",
    "type" : "task_start",
```
Event types

The response format for each event will contain one of the following event types, which is determined by the status of the event.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_start</td>
<td>Created when a task run is started.</td>
</tr>
<tr>
<td>script_start</td>
<td>Created when a script run as part of a plan is started.</td>
</tr>
<tr>
<td>command_start</td>
<td>Created when a command run as part of a plan is started.</td>
</tr>
<tr>
<td>upload_start</td>
<td>Created when a file upload as part of a plan is started.</td>
</tr>
<tr>
<td>wait_start</td>
<td>Created when a wait_until_available() call as part of a plan is started.</td>
</tr>
<tr>
<td>out_message</td>
<td>Created when out::message is called as part of a plan. details will contain a message key with a value containing the message sent with out::message truncated to 1,024 bytes. The full message content can be obtained using the GET / plan_jobs/:job-id/event/:event-id on page 543 endpoint.</td>
</tr>
<tr>
<td>apply_start</td>
<td>Created when a puppet apply run as part of a plan is started.</td>
</tr>
<tr>
<td>apply_prep_start</td>
<td>Created when an apply_prep is run as part of a plan is started.</td>
</tr>
<tr>
<td>plan_finished</td>
<td>Created when a plan job successfully finishes.</td>
</tr>
<tr>
<td>plan_failed</td>
<td>Created when a plan job fails.</td>
</tr>
</tbody>
</table>

"Sub" plans

If a plan contains the run_plan() function it will begin execution of another "sub" plan during the execution of the plan job. "Sub" plans will not receive their own plan job, they will execute as part of the original plan job. There are specific events for "sub" plans that indicate a plan within a plan has started or finished:
<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan_start</td>
<td>Created when a new plan was kicked off from the current plan job using the run_plan() function.</td>
</tr>
<tr>
<td>plan_end</td>
<td>Created when a plan started using run_plan() has finished.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> plan_end indicates the end of a &quot;sub&quot; plan (i.e. the plan job has not finished yet, but the &quot;sub&quot; plan has), while plan_finished indicates the end of a plan job.</td>
</tr>
</tbody>
</table>

### Potential values in **details**

#### task and plan actions

Includes the job-id if the event is a plan action or task (i.e. task_start, command_start, apply_start, etc).

```json
{
   "type" : "task_start",
   "details" : {
      "job-id" : 69
   },
   "id" : "80"
}
```

#### plan_finished or plan_failed

If the event type is plan_finished or plan_failed, details will include plan-id and result.

```json
{
   "type" : "plan_finished",
   "details" : {
      "result" : "plan result",
      "plan-id" : "9"
   },
   "id" : "81"
}
```

#### out_message

If the event type is out_message, details will include message.

```json
{
   "type" : "out_message",
   "details" : {
      "message" : "message sent from a plan"
   }
}
```

#### plan_start or plan_end

If the event type is plan_start or plan_end, details will include the plan that ran (plan) and plan_end will include duration.

**plan_start:**

```json
{
   "type" : "plan_start",
   "id" : "80"
}
```
"details": {
    "plan": "test::sub_plan",
    "id": "76"
} }

plan_end:
{
    "type": "plan_end",
    "details": {
        "plan": "test::sub_plan",
        "duration": 0.647551
    }
}

Error responses

See the error response documentation for the general format of error responses. For the endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the start parameter or the job-id in the request are not integers, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/unknown-job</td>
<td>If the plan job does not exist, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

GET /plan_jobs/:job-id/event/:event-id

Fetch a specific event for a job.

Response format

The response is a JSON object of the event. The following keys are available.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID of this event.</td>
</tr>
<tr>
<td>type</td>
<td>Event type.</td>
</tr>
<tr>
<td>timestamp</td>
<td>When the event occurred.</td>
</tr>
<tr>
<td>details</td>
<td>Hash of detail fields specific to the event type.</td>
</tr>
</tbody>
</table>

Note: Unlike the /plan_jobs/:job-id/events endpoint, no truncation of fields occurs.

For example:

```json
{
    "id": "1265",
    "type": "out_message",
    "timestamp": "2016-05-05T19:50:06Z",
    "details": {
        "message": "this is an output message"
    }
}
```
Error responses

See the error response documentation for the general format of error responses. For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the job-id in the request is not an integer, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/unknown-job</td>
<td>If the plan job does not exist, the server returns a 404 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/mismatched-job-event-id</td>
<td>If the event-id specified does not belong to the job-id specified, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

Puppet orchestrator API: inventory endpoint

Use the /inventory endpoint to discover which nodes can be reached by the orchestrator.

GET /inventory

List all nodes that are connected to the PCP broker.

Response format

The response is a JSON object containing a list of records for connected nodes, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the connected node.</td>
</tr>
<tr>
<td>connected</td>
<td>The connection status is either true or false.</td>
</tr>
<tr>
<td>broker</td>
<td>The PCP broker the node is connected to.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the connection was made.</td>
</tr>
</tbody>
</table>

For example:

```
{
  "items" : [
    {
      "name" : "foo.example.com",
      "connected" : true,
      "broker" : "pcp://broker1.example.com/server",
      "timestamp": "2016-010-22T13:36:41.449Z"
    },
    {
      "name" : "bar.example.com",
      "connected" : true,
      "broker" : "pcp://broker2.example.com/server",
      "timestamp": "2016-010-22T13:39:16.377Z"
    }
  ]
}
```

Error responses

For this endpoint, the kind key of the error displays the conflict.

The server returns a 500 response if the PCP broker can't be reached.
**Related information**

Puppet orchestrator API: error responses on page 574

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**GET /inventory/:node**

Return information about whether the requested node is connected to the PCP broker.

**Response format**

The response is a JSON object indicating whether the queried node is connected, using these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the connected node.</td>
</tr>
<tr>
<td>connected</td>
<td>The connection status is either true or false.</td>
</tr>
<tr>
<td>broker</td>
<td>The PCP broker the node is connected to.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the connection was made.</td>
</tr>
</tbody>
</table>

For example:

```json
{
  "name" : "foo.example.com",
  "connected" : true,
  "broker" : "pcp://broker.example.com/server",
  "timestamp" : "2017-03-29T21:48:09.633Z"
}
```

**Error responses**

For this endpoint, the kind key of the error displays the conflict.

The server returns a 500 response if the PCP broker can't be reached.

**Related information**

Puppet orchestrator API: error responses on page 574

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**POST /inventory**

Check if the given list of nodes is connected to the PCP broker.

**Request format**

The request body is a JSON object specifying a list of nodes to check. For example:

```json
{
  "nodes" : [
    "foo.example.com",
    "bar.example.com",
    "baz.example.com"
  ]
}
```

**Response format**

The response is a JSON object with a record for each node in the request, using these keys:
<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the connected node.</td>
</tr>
<tr>
<td>connected</td>
<td>The connection status is either <code>true</code> or <code>false</code>.</td>
</tr>
<tr>
<td>broker</td>
<td>The PCP broker the node is connected to.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the connection was made.</td>
</tr>
</tbody>
</table>

For example:

```
{
  "items" : [
    {
      "name" : "foo.example.com",
      "connected" : true,
      "broker" : "pcp://broker.example.com/server",
      "timestamp" : "2017-07-14T15:57:33.640Z"
    },
    {
      "name" : "bar.example.com",
      "connected" : false
    },
    {
      "name" : "baz.example.com",
      "connected" : true,
      "broker" : "pcp://broker.example.com/server",
      "timestamp" : "2017-07-14T15:41:19.242Z"
    }
  ]
}
```

**Error responses**

For this endpoint, the `kind` key of the error displays the conflict.

The server returns a 500 response if the PCP broker can't be reached.

**Related information**

- Puppet orchestrator API: error responses on page 574
  
  From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**Puppet orchestrator API: jobs endpoint**

Use the `/jobs` endpoint to examine orchestrator jobs and their details.

**GET /jobs**

List all of the jobs known to the orchestrator.

**Parameters**

The request accepts the following query parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>Return only the most recent <code>n</code> number of jobs.</td>
</tr>
<tr>
<td>offset</td>
<td>Return results offset <code>n</code> records into the result set.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Definition</td>
</tr>
<tr>
<td>-----------</td>
<td>------------</td>
</tr>
<tr>
<td>order_by</td>
<td>Return results ordered by a column. Ordering is available on owner, timestamp, environment, name, and state. Orderings requested on owner are applied to the login subfield of owner.</td>
</tr>
<tr>
<td>order</td>
<td>Indicates whether results are returned in ascending or descending order. Valid values are &quot;asc&quot; and &quot;desc&quot;. Defaults to &quot;asc&quot;</td>
</tr>
<tr>
<td>type</td>
<td>Indicates the type of job. Matches the command that created the job, which is either deploy, task, or plan_task</td>
</tr>
<tr>
<td>task</td>
<td>An optional task name to match against. Partial matches are supported. If type is specified, the task option is only allowed for task and plan_task types.</td>
</tr>
</tbody>
</table>

For example:

Response format

The response is a JSON object that lists orchestrator jobs and associated details, and uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Contains an array of all the known jobs.</td>
</tr>
<tr>
<td>id</td>
<td>An absolute URL to the given job.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the given job.</td>
</tr>
<tr>
<td>state</td>
<td>The current state of the job: new, ready, running, stopping, stopped, finished, or failed.</td>
</tr>
<tr>
<td>command</td>
<td>The command that created that job.</td>
</tr>
<tr>
<td>options</td>
<td>All of the options used to create that job. The schema of options might vary based on the command.</td>
</tr>
<tr>
<td>owner</td>
<td>The subject id and login for the user that requested the job.</td>
</tr>
<tr>
<td>description</td>
<td>(deprecated) A user-provided description of the job. For future compatibility, use the description in options.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the job state last changed.</td>
</tr>
<tr>
<td>environment</td>
<td>(deprecated) The environment that the job operates in.</td>
</tr>
<tr>
<td>node_count</td>
<td>The number of nodes the job runs on.</td>
</tr>
<tr>
<td>node_states</td>
<td>A JSON map containing the counts of nodes involved with the job by current node state. Unrepresented states are not displayed. This field is null when no nodes exist for a job.</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
</tr>
<tr>
<td>-------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>nodes</td>
<td>A link to get more information about the nodes participating in a given job.</td>
</tr>
<tr>
<td>report</td>
<td>A link to the report for a given job.</td>
</tr>
<tr>
<td>events</td>
<td>A link to the events for a given job.</td>
</tr>
</tbody>
</table>

For example:

```json
{
   "items": [
      {
         "id": "https://orchestrator.example.com:8143/orchestrator/v1/jobs/1234",
         "name": "1234",
         "state": "finished",
         "command": "deploy",
         "node_count": 5,
         "node_states": {
            "finished": 2,
            "errored": 1,
            "failed": 1,
            "running": 1
         },
         "options": {
            "concurrency": null,
            "noop": false,
            "trace": false,
            "debug": false,
            "scope": { },
            "enforce_environment": true,
            "environment": "production",
            "evaltrace": false,
            "target": null,
            "description": "deploy the web app",
         },
         "owner": {
            "id": "751a8f7e-b53a-4ccd-9f4f-e93db6aa38ec",
            "login": "brian"
         },
         "description": "deploy the web app",
         "timestamp": "2016-05-20T16:45:31Z",
         "environment": { "name": "production" },
         "report": { "id": "https://localhost:8143/orchestrator/v1/jobs/375/report" },

<td>If the job does not exist, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

**Related information**

Puppet orchestrator API: error responses on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**GET /jobs/:job-id/nodes**
List all of the nodes associated with a given job.

**Response format**
The response is a JSON object that details the nodes associated with a job.

`next-events` is an object containing information about where to find events about the job. It has the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>The url of the next event.</td>
</tr>
<tr>
<td>event</td>
<td>The next event id.</td>
</tr>
</tbody>
</table>

`items`: a list of all the nodes associated with the job, where each node has the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>(deprecated) The time of the most recent activity on the node. Prefer <code>start_timestamp</code> and <code>finish_timestamp</code></td>
</tr>
<tr>
<td>start_timestamp</td>
<td>The time the node starting running or <code>nil</code> if the node hasn't started running or was skipped</td>
</tr>
<tr>
<td>finish_timestamp</td>
<td>The time the node finished running or <code>nil</code> if the node hasn't finished running or was skipped</td>
</tr>
<tr>
<td>duration</td>
<td>The duration of the puppet run in seconds if the node has finished running, the duration in seconds that has passed after the node started running if it is currently running, or <code>nil</code> if the node hasn't started running or was skipped</td>
</tr>
<tr>
<td>state</td>
<td>The current state of the job.</td>
</tr>
<tr>
<td>transaction_uuid</td>
<td>(deprecated) The ID used to identify the nodes last report.</td>
</tr>
<tr>
<td>name</td>
<td>The hostname of the node.</td>
</tr>
<tr>
<td>details</td>
<td>information about the last event and state of a given node.</td>
</tr>
<tr>
<td>result</td>
<td>The result of a successful, failed, errored node-run. The schema of this varies.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "next-events": {
        "id": "https://orchestrator.example.com:8143/orchestrator/v1/jobs/3/events?start=10",
        "event": "10"
    },
    "items": [ {
        "timestamp": "2015-07-13T20:37:01Z",
        "start_timestamp": "2015-07-13T20:36:13Z",
```

© 2020 Puppet, Inc.
"finish_timestamp": "2015-07-13T20:37:01Z",
"duration": 48.0,
"state": "state",
"transaction_uuid": :uuid,
"name": "wss6c3w9wngpycg.example.com",
"details": {
   "message": "Message of latest event"
},
"result": {
   "output_1": "success",
   "output_2": [1, 1, 2, 3,]
}]

Results

The result field is available after a node finishes, fails, or errors and contains the contents of the details of the corresponding event. In task jobs this is the result of executing the task. For puppet jobs it contains metrics from the puppet run.

For example:

An error when running a task:

"result": {
   "msg": "Running tasks is not supported for agents older than version 5.1.0",
   "kind": "puppetlabs.orchestrator/execution-failure",
   "details": {
      "node": "copper-6"
   }
}

Raw stdout from a task:

"result": {
   "output": "test\n"
}

Structured output from a task:

"result": {
   "status": "up to date",
   "version": "5.0.0.201.g879fc5a-1.el7"
}

Error output from a task:

"result": {
   "error": "Invalid task name 'package::status'"
}

Puppet run results:

"result": {
   "hash": "d7ec44e176bb4b2e8a816157ebbae23b065b68cc",
   "noop": {
      "noop": false,
"no noop": false,
"status": "unchanged",
"metrics": {
  "corrective_change": 0,
  "out_of_sync": 0,
  "restarted": 0,
  "skipped": 0,
  "total": 347,
  "changed": 0,
  "scheduled": 0,
  "failed_to_restart": 0,
  "failed": 0
},
"environment": "production",
"configuration_version": "1502024081"
}

Using puppet apply as part of a plan results:

"result": {
  "noop": false,
  "status": "unchanged",
  "metrics": {
    "corrective_change": 0,
    "out_of_sync": 0,
    "restarted": 0,
    "skipped": 0,
    "total": 347,
    "changed": 0,
    "scheduled": 0,
    "failed_to_restart": 0,
    "failed": 0
  }
}

Details

The details field contains information based on the last event and current state of the node and can be empty. In some cases it can duplicate data from the results key for historical reasons.

If the node state is finished or failed the details hash can include a message and a report-url. (deprecated) for jobs started with the run command it also duplicates some information from the result.

{
  "items": [
    {
      "timestamp": "2015-07-13T20:37:01Z",
      "state": "finished",
      "transaction_uuid": :uuid,
      "name": "wss6c3w9wngpycg.example.com",
      "details": {
        "report-url": "https://peconsole.example.com/#/cm/report/a15bf09dd7c40705e4e1c24d0935e2e8a1591df",
        "message": "Finished puppet run on wss6c3w9wngpycg.example.com - Success!"
      }
    }
  ]
}

"result": {
  "metrics": {
    "total": 82,
    "failed": 0,
    "changed": 51,
    "skipped": 0,

© 2020 Puppet, Inc.
"restarts": 2,
"scheduled": 0,
"out_of_sync": 51,
"failed_to_restart": 0
},
},
...
}
}

If the node state is skipped or errored, the service includes a :detail key that explains why a node is in that state.

{
"items": [
  {
    "timestamp": "2015-07-13T20:37:01Z",
    "state": "failed",
    "transaction_uuid": :uuid,
    "name": "wss6c3w9wngpycg.example.com",
    "details": {
      "message": "Error running puppet on wss6c3w9wngpycg.example.com:
java.net.Exception: Something went wrong"
    }
  },
  ...
}
}

If the node state is running, the service returns the run-time (in seconds).

{
"items": [
  {
    "timestamp": "2015-07-13T20:37:01Z",
    "state": "running",
    "transaction_uuid": :uuid,
    "name": "wss6c3w9wngpycg.example.com",
    "details": {
      "run-time": 30,
      "message": "Started puppet run on wss6c3w9wngpycg.example.com..."
    }
  },
  ...
}
}

**Error responses**

For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the job-id in the request is not an integer, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/unknown-job</td>
<td>If the job does not exist, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

© 2020 Puppet, Inc.
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**GET /jobs/:job-id/report**
Returns a report for a given job.

**Response format**
The response is a JSON object that reports the status of a job, and uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>An array of all the reports associated with a given job.</td>
</tr>
<tr>
<td>node</td>
<td>The hostname of a node.</td>
</tr>
<tr>
<td>state</td>
<td>The current state of the job.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the job was created.</td>
</tr>
<tr>
<td>events</td>
<td>Any events associated with that node during the job.</td>
</tr>
</tbody>
</table>

For example:

```json
{
  "items" : [ {
    "node" : "wss6c3w9wngpycg.example.com",
    "state" : "running",
    "timestamp" : "2015-07-13T20:37:01Z",
    "events" : [ ]
  }, { ...
} ]
}
```

**Error responses**
For this endpoint, the `kind` key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the job-id in the request is not an integer, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/unknown-job</td>
<td>If the job does not exist, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

Puppet orchestrator API: error responses on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**Puppet orchestrator API: scheduled jobs endpoint**
Use the /scheduled_jobs endpoint to gather information about orchestrator jobs scheduled to run.
GET /scheduled_jobs
List scheduled jobs in ascending order.

Parameters
The request accepts the following query parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>Return only the most recent ( n ) number of jobs.</td>
</tr>
<tr>
<td>offset</td>
<td>Return results offset ( n ) records into the result set.</td>
</tr>
</tbody>
</table>

For example:

https://orchestrator.example.com:8143/orchestrator/v1/scheduled_jobs?
limit=20&offset=20

Response format
The response is a JSON object that contains a list of the known jobs and information about the pagination.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Contains an array of all the scheduled jobs.</td>
</tr>
<tr>
<td>id</td>
<td>An absolute URL to the given job.</td>
</tr>
<tr>
<td>name</td>
<td>The ID of the scheduled job</td>
</tr>
<tr>
<td>type</td>
<td>The type of scheduled job (currently only task)</td>
</tr>
<tr>
<td>task</td>
<td>The name of the task associated with the scheduled job</td>
</tr>
<tr>
<td>scope</td>
<td>The specification of the targets for the task.</td>
</tr>
<tr>
<td>environment</td>
<td>The environment that the job operates in.</td>
</tr>
<tr>
<td>owner</td>
<td>The specification for the user that requested the job.</td>
</tr>
<tr>
<td>description</td>
<td>A user-provided description of the job.</td>
</tr>
<tr>
<td>scheduled_time</td>
<td>An ISO8601 specification of when the scheduled job runs.</td>
</tr>
<tr>
<td>noop</td>
<td>True if the job runs in no-operation mode, false otherwise.</td>
</tr>
<tr>
<td>pagination</td>
<td>Contains the information about the limit, offset and total number of items.</td>
</tr>
<tr>
<td>limit</td>
<td>A restricted number of items for the request to return.</td>
</tr>
<tr>
<td>offset</td>
<td>A number offset from the start of the collection (zero based).</td>
</tr>
<tr>
<td>total</td>
<td>The total number of items in the collection, ignoring limit and offset.</td>
</tr>
</tbody>
</table>

For example:

```json
{

</tbody>
</table>

Related information

Puppet orchestrator API: error responses on page 574

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

DELETE /scheduled_jobs/:job-id

Delete a scheduled job.

- Response 204
- Response 403
  - Body

  ```json
  {
    "kind": "puppetlabs.orchestrator/not-permitted",
    "msg": "Not authorized to delete job {id}"
  }
  ```
Puppet orchestrator API: plans endpoint

Use the /plans endpoint to see all known plans in your environments.

GET /plans
List all known plans in a given environment.

Parameters

The request accepts the following query parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>Return the plans in a particular environment. Defaults to production.</td>
</tr>
</tbody>
</table>

Response format

The response is a JSON object that lists the known plans and where to find more information about them. It uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Contains an array of all known plans for the specified environment.</td>
</tr>
<tr>
<td>environment</td>
<td>A map containing the name key with the environment name and a code_id key indicating the code id the plans are listed from. Note: code_id is always null.</td>
</tr>
</tbody>
</table>

Each item above has the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL to retrieve plan details.</td>
</tr>
<tr>
<td>name</td>
<td>The full name of the plan.</td>
</tr>
<tr>
<td>permitted</td>
<td>A boolean indicating if the user making the request is permitted to use the plan.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "environment": {
        "name": "production",
        "code_id": null
    },
    "items": [
        {
            "id": "https://orchestrator.example.com:8143/orchestrator/v1/plans/profile/firewall",
            "name": "profile::firewall",
            "permitted": true
        },
        {
```
Error responses

For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the environment parameter is not a legal environment name, the server returns a 400 response.</td>
</tr>
<tr>
<td>puppetlabs.orchestrator/unknown-environment</td>
<td>If the specified environment doesn’t exist, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

GET /plans/:module/:planname

Return data about the specified plan, including metadata.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>Return the plan from a particular environment. Defaults to production.</td>
</tr>
<tr>
<td></td>
<td>Note: code_id is always null.</td>
</tr>
</tbody>
</table>

Response format

The response is a JSON object that includes information about the specified plan. The following keys are used:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL to retrieve plan details.</td>
</tr>
<tr>
<td>name</td>
<td>The full name of the plan.</td>
</tr>
<tr>
<td>environment</td>
<td>A map containing a name key with the environment name and a code_id key indicating the code id the plan is being listed from.</td>
</tr>
<tr>
<td>metadata</td>
<td>Currently always an empty object.</td>
</tr>
<tr>
<td>permitted</td>
<td>A boolean indicating if the user is permitted to use the plan or not.</td>
</tr>
</tbody>
</table>

For example:

```
{
  "id": "https://orchestrator.example.com:8143/orchestrator/v1/plans/package/install",
```
"name": "canary::random",
"environment": {
  "name": "production",
  "code_id": null
},
"metadata": {},
"permitted": true
}

Error responses

</tr>
</tbody>
</table>

Puppet orchestrator API: plan jobs endpoint

Use the /plan_jobs endpoint to view details about plan jobs you have run.

GET /plan_jobs
List the known plan jobs sorted by name and in descending order.

Parameters

The request accepts the following query parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>Return only the most recent n number of jobs.</td>
</tr>
<tr>
<td>offset</td>
<td>Return results offset n records into the result set.</td>
</tr>
<tr>
<td>results</td>
<td>Whether to include or exclude the plan output for each plan in the list. The default is include</td>
</tr>
</tbody>
</table>

Response format

The response is a JSON object that contains a list of the known plan jobs, and information about the pagination.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>An array of all the plan jobs.</td>

GET /plan_jobs/:job-id
List all the details of a given plan job.

Response format
The response is a JSON object that lists all details of a given plan job. The following keys are used:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL to the given plan job.</td>
</tr>
<tr>
<td>name</td>
<td>The ID of the plan job.</td>
</tr>
<tr>
<td>state</td>
<td>The current state of the plan job: running, success, or failure</td>
</tr>
<tr>
<td>options</td>
<td>Information about the plan job: description, plan_name, and any parameters.</td>
</tr>
<tr>
<td>description</td>
<td>The user-provided description for the plan job.</td>
</tr>
<tr>
<td>plan_name</td>
<td>The name of the plan that was run, for example package::install.</td>
</tr>
<tr>
<td>parameters</td>
<td>The parameters passed to the plan for the job.</td>
</tr>
<tr>
<td>result</td>
<td>The output from the plan job.</td>
</tr>
<tr>
<td>owner</td>
<td>The subject ID and login for the user that requested the job.</td>
</tr>
<tr>
<td>timestamp</td>
<td>The time when the plan job state last changed.</td>
</tr>
<tr>
<td>created_timestamp</td>
<td>The time the plan job was created.</td>
</tr>
<tr>
<td>finished_timestamp</td>
<td>The time the plan job finished.</td>

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

Puppet orchestrator API: tasks endpoint

Use the /tasks endpoint to view details about the tasks pre-installed by PE and those you've installed.
GET /tasks
Lists all tasks in a given environment.

Parameters
The request accepts this query parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>Returns the tasks in the specified environment. If unspecified, defaults to production.</td>
</tr>
</tbody>
</table>

Response format
The response is a JSON object that lists each known task with a link to additional information, and uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>A map containing a name key specifying the environment's name and a code_id key indicating the code ID where the task is listed.</td>
</tr>
<tr>
<td>items</td>
<td>Contains an array of all known tasks.</td>
</tr>
<tr>
<td>id</td>
<td>An absolute URL where the task's details are listed.</td>
</tr>
<tr>
<td>name</td>
<td>The full name of the task.</td>
</tr>
</tbody>
</table>

```json
{
  "environment": {
    "name": "production",
    "code_id": "urn:puppet:code-id:1:a86da166c30f871823f9b2ea224796e834840676;production"
  },
  "items": [
    {
      "id": "https://orchestrator.example.com:8143/orchestrator/v1/tasks/package/install",
      "name": "package::install"
    },
    {
      "id": "https://orchestrator.example.com:8143/orchestrator/v1/tasks/package/upgrade",
      "name": "package::upgrade"
    },
    {
      "id": "https://orchestrator.example.com:8143/orchestrator/v1/tasks/exec/init",
      "name": "exec"
    }
  ]
}
```

Error responses
For this endpoint, the kind key of the error displays the conflict.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppetlabs.orchestrator/validation-error</td>
<td>If the environment parameter is not a legal environment name, the server returns a 400 response.</td>
</tr>
</tbody>
</table>
Key | Definition
--- | ---
puppetlabs.orchestrator/unknown-environment | If the specified environment doesn’t exist, the server returns a 404 response.

**Related information**
Puppet orchestrator API: error responses on page 574

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**GET /tasks/:module/:taskname**
Returns data about a specified task, including metadata and file information. For the default task in a module, :taskname is init.

**Parameters**
The request accepts this query parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>environment</td>
<td>Returns the tasks in the specified environment. If unspecified, defaults to production.</td>
</tr>
</tbody>
</table>

**Response format**
The response is a JSON object that includes information about the specified task, and uses these keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL where the task's details are listed.</td>
</tr>
<tr>
<td>name</td>
<td>The full name of the task.</td>
</tr>
<tr>
<td>environment</td>
<td>A map containing a name key specifying the environment's name and a code_id key indicating the code ID where the task is listed.</td>
</tr>
<tr>
<td>metadata</td>
<td>A map containing the contents of the &lt;task&gt;.json file.</td>
</tr>
<tr>
<td>files</td>
<td>An array of the files in the task.</td>
</tr>
<tr>
<td>filename</td>
<td>The base name of the file.</td>
</tr>
<tr>
<td>uri</td>
<td>A map containing path and params fields to construct a URL to download the file content. The client determines which host to download the file from.</td>
</tr>
<tr>
<td>sha256</td>
<td>The SHA-256 hash of the file content, in lowercase hexadecimal form.</td>
</tr>
<tr>
<td>size_bytes</td>
<td>The size of the file content in bytes.</td>
</tr>
</tbody>
</table>

For example:

```json
{  
  "id": "https://orchestrator.example.com:8143/orchestrator/v1/tasks/package/install",  
  "name": "package::install",  
  "environment": {  
    "name": "production",  
  }
```
"code_id": "urn:puppet:code-id:1:a86da166c30f871823f9b2ea224796e834840676;production",
"metadata": {
  "description": "Install a package",
  "supports_noop": true,
  "input_method": "stdin",
  "parameters": {
    "name": {
      "description": "The package to install",
      "type": "String[1]"
    },
    "provider": {
      "description": "The provider to use to install the package",
      "type": "Optional[String[1]]"
    },
    "version": {
      "description": "The version of the package to install, defaults to latest",
      "type": "Optional[String[1]]"
    }
  }
},
"files": [
  {
    "filename": "install",
    "uri": {
      "path": "/package/tasks/install",
      "params": {
        "environment": "production"
      }
    },
    "sha256": "a9089b5b9720dca38a49db6f164cf8a053a7ea528711325da1c23de94672980f",
    "size_bytes": 693
  }
]
}

Puppet orchestrator API: error responses on page 574
From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**Puppet orchestrator API: root endpoint**

Use the `/orchestrator` endpoint to return metadata about the orchestrator API.

**GET /orchestrator**

A request to the root of the Puppet orchestrator returns metadata about the orchestrator API, along with a list of links to application management resources.

**Response format**

Responses use the following format:

```json
{
  "info": {
    "title": "Application Management API (EXPERIMENTAL)",
    "description": "Multi-purpose API for performing application management operations",
    "warning": "This version of the API is experimental, and might change in backwards-incompatible ways in the future",
    "version": "0.1",
    "license": {
      "name": "Puppet Enterprise License",
      "url": "https://puppetlabs.com/puppet-enterprise-components-licenses"
    }
  },
  "status": {
    "name": "status",
    "id": "https://orchestrator.example.com:8143/orchestrator/v1/status"
  },
  "collections": [
    { "name": "environments",
      "id": "https://orchestrator.example.com:8143/orchestrator/v1/environments"

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**Puppet orchestrator API: usage endpoint**

Use the /usage endpoint to view details about the active nodes in your deployment.

**GET /usage**

List the daily node usage of the orchestrator and nodes that are present in PuppetDB.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>start_date</td>
<td>Expected to be in the format YYYY-MM-DD, the first day to include in the result</td>
</tr>
<tr>
<td>end_date</td>
<td>Expected to be in the format YYYY-MM-DD, the last day to include in the result must be &gt;= start_date</td>
</tr>
</tbody>
</table>

**Response format**

The response is a JSON object indicating the total number of active nodes and subtotals of the nodes with and without an agent installed.

The following keys are used:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Contains an array entries from most recent to least recent.</td>
</tr>
<tr>
<td>• date</td>
<td>An ISO 8601 date representing the date of the request in UTC.</td>
</tr>
<tr>
<td>• total_nodes</td>
<td>The total number of nodes used since UTC midnight.</td>
</tr>
<tr>
<td>• nodes_with_agent</td>
<td>The number of nodes in pdb at the time the request is made.</td>
</tr>
<tr>
<td>• nodes_without_agent</td>
<td>The number of unique nodes that don't have an agent that were used since UTC midnight.</td>
</tr>
<tr>
<td>• corrective_agent_changes</td>
<td>The number of corrective changes made by agent runs.</td>
</tr>
<tr>
<td>• intentional_agent_changes</td>
<td>The number of intentional changes made by agent runs.</td>
</tr>
<tr>
<td>• nodes_affected_by_task_runs</td>
<td>The number of tasks run (counted per node that a task runs on).</td>
</tr>
<tr>
<td>• nodes_affected_by_plan_runs</td>
<td>The number of plans run (counted per node that a plan runs on).</td>
</tr>
<tr>
<td>pagination</td>
<td>An optional object that includes information about the original query.</td>
</tr>
<tr>
<td>• start_date</td>
<td>The starting day for the request (if specified).</td>
</tr>
</tbody>
</table>
### Key

<table>
<thead>
<tr>
<th>Key</th>

```

### Error Responses

For this endpoint, the kind key of the error displays the conflict.

### Related information

**Puppet orchestrator API: error responses** on page 574

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

**Puppet orchestrator API: scopes endpoint**

Use the scopes endpoint to retrieve resources for task constraints.

**GET /scopes/task_targets**

List all the known task targets (set of tasks + set of nodes + set of node groups) stored in orchestrator.

**Response format**

The response is a JSON object that lists the known task targets and uses the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Contains an array of all the known task targets.</td>
</tr>
</tbody>
</table>

The following keys are included under items:
**Key** | **Definition**
---|---
id | An absolute URL to retrieve the individual task target.
name | A string that is a unique identifier for the task target.
display_name | An optional string value that can be used to describe the task target.
tasks | An optional array of tasks that this task target corresponds to.
all_tasks | An optional boolean to determine if all tasks can be run on designated targets.
nodes | An array of certnames that this task target corresponds to. The array can be empty.
node_groups | An array of node group ids that this task target corresponds to. The array can be empty.
pql_query | (optional) A string that is a single PQL query that the task target corresponds to.

For example:

```json
{
   "items": [
      {
         "id": "https://orchestrator.example.com:8143/orchestrator/v1/scopes/task_targets/1",
         "name": "1",
         "tasks": [
            "package::install",
            "exec"
         ],
         "all_tasks": "false",
         "nodes": [
            "wss6c3w9wmgzycg",
            "jjv2h5w8gpycgw"
         ],
         "node_groups": [
            "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
            "493b2be7-69c4-412f-b15c-ac0a7c2883f1"
         ],
         "pql_query": "nodes[certname] { catalog_environment = "production" }"
      },
      {
         "id": "https://orchestrator.example.com:8143/orchestrator/v1/scopes/task_targets/2",
         "name": "2",
         "tasks": [
            "imaginary::task"
         ],
         "all_tasks": "false",
         "nodes": [
            "mynode"
         ],
         "node_groups": []
      },
      {
         "id": "https://orchestrator.example.com:8143/orchestrator/v1/scopes/task_targets/3",
         "name": "3",
```
GET /scopes/task_targets/:id
Get information about a specific task_target.

Response format
The response is a JSON object that provides the details about the task_target and uses the following keys:

<table>
<thead>
<tr>
<th>Keys</th>
<th>Definitions</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>An absolute URL to retrieve the individual task_target.</td>
</tr>
<tr>
<td>name</td>
<td>A string that is a unique identifier for the task_target.</td>
</tr>
<tr>
<td>display_name</td>
<td>An optional string value that can be used to describe the task_target.</td>
</tr>
<tr>
<td>tasks</td>
<td>An optional array of tasks that this task_target corresponds to.</td>
</tr>
<tr>
<td>all_tasks</td>
<td>An optional boolean to determine if all tasks can be run on designated targets.</td>
</tr>
<tr>
<td>nodes</td>
<td>An array of certnames that this task_target corresponds to. The array can be empty.</td>
</tr>
<tr>
<td>node_groups</td>
<td>An array of node group ids that this task_target corresponds to. The array can be empty.</td>
</tr>
<tr>
<td>pql_query</td>
<td>(optional) A string that is a single PQL query that the task_target corresponds to.</td>
</tr>
</tbody>
</table>

For example:

```json
{
    "id": "https://orchestrator.example.com:8143/orchestrator/v1/scopes/task_targets/1",
    "name": "1",
    "tasks": [
        "package::install",
        "exec"
    ],
    "all_tasks": "false",
    "nodes": [
        "wss6c3w9wngpycg",
        "jjj2h5w8gpycgwn"
    ],
    "node_groups": [
        "3c4df64f-7609-4d31-9c2d-acfa52ed66ec",
        "4932bfe7-69c4-412f-b15c-ac0a7c2883f1"
    ]
}
```
"pql_query": "nodes[certname] { catalog_environment = \"production\" }"
}

Error responses

For this endpoint, the kind key of the error displays the conflict. See the Puppet orchestrator API: error responses on page 574 documentation for the general format of error responses.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>:puppetlabs.orchestrator/unknown-task-target</td>
<td>If the specified id doesn't exist, the server returns a 404 response.</td>
</tr>
</tbody>
</table>

Puppet orchestrator API: error responses

From time to time, you might encounter an error using the orchestrator API. In such cases, you receive an error response.

Every error response from the Puppet orchestrator is a JSON response. Each response is an object that contains the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>The kind of error encountered.</td>
</tr>
<tr>
<td>msg</td>
<td>The message associated with the error.</td>
</tr>
<tr>
<td>details</td>
<td>A hash with more information about the error.</td>
</tr>
</tbody>
</table>

For example, if an environment does not exist for a given request, an error is raised similar to the following:

```json
{
  "kind" : "puppetlabs.orchestrator/unknown-environment",
  "msg" : "Unknown environment doesnotexist",
  "details" : {
    "environment" : "doesnotexist"
  }
}
```

Migrating Bolt tasks and plans to PE

If you use Bolt tasks and plans to automate parts of your configuration management, you can move that Bolt content to a control repo and transform it into a PE environment. This lets you manage and run tasks and plans using PE and the console. PE environments and Bolt projects use the same default structure, and both use a Puppetfile to install content.

The control repo is a central Git repository PE fetches content from. An environment is a space for PE authors to write and install content, similar to a Bolt project.

There are two ways to get your Bolt content into an environment:

- Move your Bolt code to a new control repo. Do this if you have a Bolt dir, or an embedded project directory, in a repo that also contains other code that you do not wish to migrate to PE.
- Configure PE to point to the Bolt project. Do this if you have a dedicated repo for Bolt code, or a local project directory, and don't want to duplicate it in PE.
Move Bolt content to a new PE repo

Move your Bolt project content out of your Bolt dir and into a fresh PE control repo.

Before you begin

- Install PE on your machine. See Getting started with Puppet Enterprise on page 52.
- Set up your PE control repo and environments. See Managing environments with a control repository on page 578.

To move Bolt content to a repo:

1. Commit the contents of your Bolt project to a branch of your PE control repo.

   Your new structure is similar to the local project directory in Bolt, for example:

   ```
   project/
   ### Puppetfile
   ### bolt.yaml
   ### data
   #   ### common.yaml
   ### inventory.yaml
   ### site-modules
   ### project
   ### manifests
   #   ### my_class.pp
   ### plans
   #   ### deploy.pp
   #   ### diagnose.pp
   ### tasks
   #   ### init.json
   ### init.py
   ```

2. Create a configuration file called environment.conf and add it to the root directory of the branch. This file configures the environment in PE.

3. Add the modulepath setting to the environment.conf file by adding the following line:

   ```
   modulepath = modules:site-modules:$basemodulepath
   ```

   **Note**: PE picks up modules only from the modules directory. It's important to add site-modules to the modulepath setting so it matches the defaults for your Bolt project. If you have a modulepath setting in bolt.yaml, match it to the modulepath setting in environment.conf.

4. Publish the branch to the PE control repo.

5. Deploy code using puppet code deploy --<ENVIRONMENT>, where <ENVIRONMENT> is the name of your branch, to commit the new branch to Git.

   **Note**: You can also deploy code using a webhook. See Triggering Code Manager with a webhook on page 606 for more information.

After you deploy code, modules, and the tasks and plans within them, listed in the new environment’s Puppetfile will be available to use in PE.

Related information

Plan caveats and limitations on page 474
Some plan language and features are not available in PE or have some caveats.

Point PE to a Bolt project

Allow PE to manage content in your dedicated Bolt repo.

Before you begin

- Install PE on your machine. See Getting started with Puppet Enterprise on page 52.
• Ensure your Bolt project follows the local project directory structure.

To point PE to your Bolt content:

1. Generate a private SSH key to allow access to the control repository.

   This SSH key cannot require a password.

   a) Generate the key pair:

   ```
   ssh-keygen -t rsa -b 2048 -P '' -f /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   ```

   b) Set appropriate permissions so that the pe-puppet user can access the key:

   ```
   puppet infrastructure configure
   ```

   Your keys are now located in /etc/puppetlabs/puppetserver/ssh:

   • Private key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   • Public key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa.pub

   Configure your Git host to use the SSH public key you generated. The process to do this is different for every Git host. Usually, you create a user or service account, and then assign the SSH public key to it.

   Code management needs read access to your control repository, as well as any module repositories referenced in the Puppetfile.

   See the your Git host docs for detailed instructions on adding SSH keys to your Git server. Commonly used Git hosts include:

   • GitHub
   • BitBucket Server
   • GitLab

2. Change the name of your branch to production. PE uses branches in Git as environments and the default environment is production.

3. Create a configuration file called environment.conf and add it to the root directory of the branch. This file configures the environment.

4. Add the modulepath setting to the environment.conf file by adding the following line:

   ```
   modulepath = modules:site-modules:$basemodulepath
   ```

   **Note:** Without this setting, PE picks up modules only from the modules directory. It's important to add site-modules to the modulepath setting so it matches the defaults for your Bolt project. If you have a modulepath setting in bolt.yaml, match it to the modulepath setting in environment.conf.

5. Publish the branch to the PE control repo.

6. Deploy code using puppet code deploy --<ENVIRONMENT>, where <ENVIRONMENT> is the name of your branch, to commit the new branch to git.

   **Note:** You can also deploy code using a webhook. See Triggering Code Manager with a webhook on page 606 for more information.

After you deploy code, modules, and the tasks and plans within them, listed in the new environment's Puppetfile will be available to use in PE.

**Related information**

Plan caveats and limitations on page 474

© 2020 Puppet, Inc.
Some plan language and features are not available in PE or have some caveats.

PE workflows for Bolt users
Review these differences between PE and Bolt commands and workflows before you start running tasks and plans in PE.

Connecting to nodes
You must connect PE to each node you want to run tasks on or include in a plan. See Add nodes to the inventory on page 54 for instructions on how to add agent or agentless nodes to your inventory.

Installing tasks and plans
In PE, as in Bolt, you use the `mod` command to download modules. But instead of running the `bolt puppetfile install` command to install them, you trigger Code Manager and deploy code using the `puppet code deploy` command. See Triggering Code Manager on the command line on page 601 for more information.

Running tasks and plans
PE does not recognize the `bolt` command for running tasks and plans. Instead, use the `puppet task run` and `puppet plan run` commands, or use the console. To run tasks or plans from the command line, see:
- Running tasks from the command line on page 466
- Running plans from the command line on page 473

To run tasks or plans from the console, see:
- Running tasks from the console on page 460
- Running plans from the console on page 472

Limitations in PE
Not everything in Bolt works in PE. For example, many pre-installed Bolt modules are not included in PE and many plan functions like `file::exists` and `set_feature` do not work. See Plan caveats and limitations on page 474 for more information.

Managing and deploying Puppet code
Puppet Enterprise (PE) includes built-in tools for managing and deploying your Puppet infrastructure. Code Manager and r10k are code management tools that automatically install modules, create and maintain environments, and deploy new code to your masters, all based on version control of your Puppet code and data.

Code management tools use Git version control to track, maintain, and deploy your Puppet modules, manifests, and data. This allows you to more easily maintain, update, review, and deploy Puppet code and data for multiple environments.

Code Manager automates the deployment of your Puppet code and data. You make code and data changes on your workstation, push changes to your Git repository, and then Code Manager creates environments, installs modules, and deploys the new code to your masters, without interrupting agent runs.

If you are already using r10k to manage your Puppet code, we suggest that you upgrade to Code Manager. Code Manager works in concert with r10k, so when you switch to Code Manager, you no longer interact directly with r10k.

If you’re using r10k and aren’t ready to switch to Code Manager yet, you can continue using r10k alone. You push your code changes to your version control repo, deploy environments from the command line, and r10k creates environments and installs the modules for each one.
Both Code Manager and the r10k code management tool are built into PE, so you don’t have to install anything. To begin managing your code with either of these tools, you perform the following tasks:

1. Create a control repository with Git for maintaining your environments and code.
   The control repository is the Git repository that code management uses to maintain and deploy your Puppet code and data and to create environments in your Puppet infrastructure. As you update your control repo, code management keeps each of your environments updated.

2. Set up a Puppetfile to manage content in your environment.
   This file specifies which modules and data to install in your environment, including what version of that content to install, and where to download the content from.

3. Configure Code Manager (recommended) or r10k.
   Configure code management in the console’s master profile. If you need to customize your configuration further, you can do so by adding keys to Hiera.

4. Deploy environments. With Code Manager, either set up a deployment trigger (recommended), or plan to trigger your deployment from the command line, which is useful for initial configuration. If you are using r10k alone, run it from the command line whenever you want to deploy.

The following sections go into detail about setting up and using Code Manager and r10k.

• Managing environments with a control repository on page 578
To manage your Puppet code and data with either Code Manager or r10k, you need a Git version control repository. This control repository is where code management stores code and data to deploy your environments.

• Managing environment content with a Puppetfile on page 583
A Puppetfile specifies detailed information about each environment’s Puppet code and data, including where to get that code and data from, where to install it, and whether to update it.

• Managing code with Code Manager on page 588
Code Manager automates the management and deployment of your Puppet code. Push code updates to your source control repo, and then Puppet syncs the code to your masters, so that all your servers start running the new code at the same time, without interrupting agent runs.

• Managing code with r10k on page 623
r10k is a code management tool that allows you to manage your environment configurations (such as production, testing, and development) in a source control repository.

• About file sync on page 635
File sync helps Code Manager keep your Puppet code synchronized across multiple masters.

Managing environments with a control repository

To manage your Puppet code and data with either Code Manager or r10k, you need a Git version control repository. This control repository is where code management stores code and data to deploy your environments.

How the control repository works

Code management relies on version control to track, maintain, and deploy your Puppet code and data. The control repository (or repo) is the Git repository that code management uses to manage environments in your infrastructure. As you update code and data in your control repo, code management keeps each of your environments updated.

Code management creates and maintains your environments based on the branches in your control repo. For example, if your control repo has a production branch, a development branch, and a testing branch, code management creates a production environment, a development environment, and a testing environment, each with its own version of your Puppet code and data.

Environments are created in /etc/puppetlabs/code/environments on the master. To learn more about environments in Puppet, read the documentation about environments.

To create a control repo that includes the standard recommended structure, code examples, and configuration scripts, base your control repo on the Puppet control repo template. This template covers most customer situations. If you
cannot access the internet or cannot use modules directly from the Forge because of your organization’s security rules, create an empty control repo and add the files you need to it.

**Note:** For Windows systems, be sure your version control is configured to use CRLF line endings. See your version control system for instructions on how to do this.

At minimum, a control repo comprises:

- A Git remote repository. The remote is where your control repo is stored on your Git host.
- A default branch named `production`, rather than the usual Git default of `master`.
- A Puppetfile to manage your environment content.
- An `environment.conf` file that modifies the `$modulepath` setting to allow environment-specific modules and settings.

**CAUTION:** Enabling code management means that Puppet manages the environment directories and **existing environments are not preserved**. Environments with the same name as the new one are overwritten. Environments not represented in the control repo are erased. If you were using environments before, commit any necessary files or code to the appropriate new control repo branch, or back them up somewhere **before** you start configuring code management.

### Create a control repo from the Puppet template

To create a control repo that includes a standard recommended structure, code examples, and configuration scripts, base your control repo on the Puppet control repo template. This template covers most customer situations.

To base your control repo on the Puppet control repository template, you copy the control repo template to your development workstation, set your own remote Git repository as the default source, and then push the template contents to that source.

The control repo template contains the files needed to get you started with a functioning control repo, including:

- An `environment.conf` file to implement a `site-modules/` directory for roles, profiles, and custom modules.
- `config_version` scripts to notify you which control repo version was applied to the agents.
- Basic code examples for setting up roles and profiles.
- An example `hieradata` directory that matches the default hierarchy.
- A Puppetfile to manage content maintained in your environment.

Set up a private SSH key so that your master can identify itself to your Git host.
1. Generate a private SSH key to allow access to the control repository.
   This SSH key cannot require a password.
   a) Generate the key pair:

   ```bash
   ssh-keygen -t rsa -b 2048 -P '' -f /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   ```

   b) Set appropriate permissions so that the pe-puppet user can access the key:

   ```bash
   puppet infrastructure configure
   ```

   Your keys are now located in /etc/puppetlabs/puppetserver/ssh:
   
   - Private key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   - Public key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa.pub

   Configure your Git host to use the SSH public key you generated. The process to do this is different for every Git host. Usually, you create a user or service account, and then assign the SSH public key to it.

   Code management needs read access to your control repository, as well as any module repositories referenced in the Puppetfile.

   See the your Git host docs for detailed instructions on adding SSH keys to your Git server. Commonly used Git hosts include:
   
   - GitHub
   - BitBucket Server
   - GitLab

2. Create a repository in your Git account, with the name you want your control repo to have.

   Steps for creating a repository vary, depending on what Git host you are using (GitHub, GitLab, Bitbucket, or another provider). See your Git host's documentation for complete instructions.

   For example, on GitHub:
   
   a) Click + at the top of the page, and choose New repository.
   b) Select the account Owner for the repository.
   c) Name the repository (for example, control-repo).
   d) Note the repository's SSH URL for later use.

3. If you don't already have Git installed, run the following command on your master:

   ```bash
   yum install git
   ```

4. From the command line, clone the Puppet control-repo template.

   ```bash
   git clone https://github.com/puppetlabs/control-repo.git
   ```

5. Change directory into your contro repo.

   ```bash
   cd <NAME OF YOUR CONTROL REPO>
   ```

6. Remove the template repository as your default source.

   ```bash
   git remote remove origin
   ```

7. Add the control repository you created as the default source.

   ```bash
   git remote add origin <URL OF YOUR GIT REPOSITORY>
   ```
8. Push the contents of the cloned control repo to your remote copy of the control repo:

    git push origin production

You now have a control repository based on the Puppet control-repo template. When you make changes to this repo on your workstation and push those changes to the remote copy of the control repo on your Git server, Code Manager deploys your infrastructure changes.

You also now have a Puppetfile available for you to start adding and managing content, like module code.

Create an empty control repo

If you can't use the control repo template because, for example, you cannot access the internet or use modules directly from the Forge because of your security rules, create an empty control repo and then add the files you need.

To start with an empty control repo, you create a new repo on your Git host and then copy it to your workstation. You make some changes to your repo, including adding a configuration file that allows code management tools to find modules in both your site and environment-specific module directories. When you're done making changes, push your changes to your repository on your Git host.

1. Generate a private SSH key to allow access to the control repository.
   This SSH key cannot require a password.
   a) Generate the key pair:

       ssh-keygen -t rsa -b 2048 -P '' -f /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa

   b) Set appropriate permissions so that the pe-puppet user can access the key:

       puppet infrastructure configure

   Your keys are now located in /etc/puppetlabs/puppetserver/ssh:
   • Private key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa
   • Public key: /etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa.pub

   Configure your Git host to use the SSH public key you generated. The process to do this is different for every Git host. Usually, you create a user or service account, and then assign the SSH public key to it.

   Code management needs read access to your control repository, as well as any module repositories referenced in the Puppetfile.

   See the your Git host docs for detailed instructions on adding SSH keys to your Git server. Commonly used Git hosts include:

   • GitHub
   • BitBucket Server
   • GitLab

2. Create a repository in your Git account, with the name you want your control repo to have.

   Steps for creating a repository vary, depending on what Git host you are using (GitHub, GitLab, Bitbucket, or another provider). See your Git host's documentation for complete instructions.

   For example, on GitHub:
   a) Click + at the top of the page, and choose New repository.
   b) Select the account Owner for the repository.
   c) Name the repository (for example, control-repo).
   d) Note the repository's SSH URL for later use.

3. Clone the empty repository to your workstation by running git clone <REPOSITORY URL>

4. Create a file named environment.conf in the main directory of your control repo.
5. In your text editor, open `environment.conf` file, and add the line below to set the modulepath. Save and close the file.

```plaintext
modulepath=site-modules:modules:$basemodulepath
```

6. Add and commit your change to the repository by running:
   a) `git add environment.conf`
   b) `git commit -m "add environment.conf"

The `environment.conf` file allows code management tools to find modules in both your site and environment-specific module directories. For details about this file, see the `environment.conf` documentation.

7. Rename the `master` branch to `production` by running `git branch -m master production`

   **Important:** The default branch of a control repo must be `production`.

8. Push your repository's `production` branch from your workstation to your Git host by running `git push -u origin production`

When you make changes to this repo on your workstation, push those changes to the remote copy of the control repo on your Git server, so that code management can deploy your infrastructure changes.

After you've set up your control repo, create a Puppetfile for managing your environment content with code management.

If you already have a Puppetfile, you can now configure code management. Code management configuration steps differ, depending on whether you're using Code Manager (recommended) or r10k. For important information about the function and limitations of each of these tools, along with configuration instructions, see the Code Manager and r10k pages.

### Add an environment

Create new environments by creating branches based on the production branch of your control repository.

**Before you begin**

Make sure you have:

- Configured either Code Manager or r10k.
- Created a Puppetfile in the default (usually 'production') branch of your control repo.
- Selected your code management deployment method (such as the `puppet-code` command or a webhook).

**Remember:** If you are using multiple control repos, do not duplicate branch names unless you use a source prefix. For more information about source prefixes, see the documentation about configuring sources.

1. Create a new branch: `git branch <NAME-OF-NEW-BRANCH>`
2. Check out the new branch: `git checkout <NAME-OF-NEW-BRANCH>`
3. Edit the Puppetfile to track the modules and data needed in your new environment, and save your changes.
4. Commit your changes: `git commit -m "a commit message summarizing your change"`
5. Push your changes: `git push origin <NAME-OF-NEW-BRANCH>`
6. Deploy your environments as you normally would, either on the command line or with a Code Manager webhook.

### Delete an environment with code management

To delete an environment with Code Manager or r10k, delete the corresponding branch from your control repository.

1. On the production branch of your control repo directory, on the command line, delete the environment's corresponding remote branch by running `git push origin --delete <BRANCH-TO-DELETE>`
2. Delete the local branch by running `git branch -d <BRANCH-TO-DELETE>`

© 2020 Puppet, Inc.
3. Deploy your environments as you normally would, either on the command line or with a Code Manager webhook.

   **Note:** If you use Code Manager to deploy environments with the webhook, deleting a branch from your control repository does not immediately delete that environment from the master's live code directories. Code Manager deletes the environment when it next deploys changes to any other environment. Alternately, to delete the environment immediately, deploy all environments manually: `puppet-code deploy --all --wait`

---

**Managing environment content with a Puppetfile**

A Puppetfile specifies detailed information about each environment's Puppet code and data, including where to get that code and data from, where to install it, and whether to update it.

Both Code Manager and r10k use a Puppetfile to install and manage the content of your environments.

**The Puppetfile**

The Puppetfile specifies the modules and data that you want in each environment. The Puppetfile can specify what version of modules you want, how the modules and data are to be loaded, and where they are placed in the environment.

A Puppetfile is a formatted text file that specifies the modules and data that you want brought into your control repo. Typically, a Puppetfile controls content such as:

- Modules from the Forge
- Modules from Git repositories
- Data from Git repositories

For each environment that you want to manage content in, you need a Puppetfile. Create a base Puppetfile in your default environment (usually `production`). As you create new branches based on your default branch, each environment inherits this base Puppetfile. You can then edit each environment's Puppetfile as needed.

**Managing modules with a Puppetfile**

With code management, install and manage your modules only with a Puppetfile.

Almost all Puppet manifests are kept in modules, collections of Puppet code and data with a specific directory structure. By default, Code Manager and r10k install content in a modules directory (`./modules`) in the same directory the Puppetfile is in. For example, declaring the `puppetlabs-apache` module in the Puppetfile normally installs the module into `./modules/apache`. To learn more about modules, see the module documentation.

**Important:**

With Code Manager and r10k, **do not** use the `puppet module` command to install or manage modules. Instead, code management depends on the Puppetfile in each of your environments to install, update, and manage your modules. If you've installed modules to the live code directory with `puppet module install`, Code Manager deletes them.

The Puppetfile does **NOT** include Forge module dependency resolution. You must make sure that you have every module needed for all of your specified modules to run. In addition, Forge module symlinks are unsupported; when you install modules with r10k or Code Manager, symlinks are not installed.

**Including your own modules**

If you develop your own modules, maintain them in version control and include them in your Puppetfile as you would declare any module from a repository. If you have content in your control repo's module directory that is **not** listed in your Puppetfile, code management purges it. (The control repo module directory is, by default, `./modules` relative to the location of the Puppetfile.)

© 2020 Puppet, Inc.
Deploying code

When you install or update a module, you must trigger Code Manager or r10k to deploy the new or updated code to your environments.

With Code Manager, you can deploy code on the command line or using a webhook:
- Triggering Code Manager on the command line on page 601
- Triggering Code Manager with a webhook on page 606

With r10k, you can deploy code using the command line:
- Deploying environments with r10k on page 632

Creating a Puppetfile

Your Puppetfile manages the content you want to maintain in that environment.

In a Puppetfile, you can declare:
- Modules from the Forge.
- Modules from a Git repository.
- Data or other non-module content (such as Hiera data) from a Git repository.

You can declare any or all of this content as needed for each environment. Each module or repository is specified with a `mod` directive, along with the name of the content and other information the Puppetfile needs so that it can correctly install and update your modules and data.

It's best to create your first Puppetfile in your production branch. Then, as you create branches based on your production branch, edit each branch's Puppetfile as needed.

Create a Puppetfile

Create a Puppetfile that manages the content maintained in your environment.

Before you begin

Set up a control repo, with production as the default branch. To learn more about control repositories, see the control repository documentation.

Create a Puppetfile in your production branch, and then edit it to declare the content in your production environment with the `mod` directive.

1. On your production branch, in the root directory, create a file named `Puppetfile`.
2. In a text editor, for example Visual Studio Code (VS Code), edit the Puppetfile, declaring modules and data content for your environment. Note that Puppet has an extension for VS Code that supports syntax highlighting of the Puppet language.

You can declare modules from the Forge or you can declare Git repositories in your Puppetfile. See the related topics about declaring content in the Puppetfile for instructions.

Configure Code Manager or r10k.

Change the Puppetfile module installation directory

If needed, you can change the directory to which the Puppetfile installs all modules.

To specify a module installation path other than the default modules directory (.modules), use the `moduledir` directive.

This directive applies to all content declared in the Puppetfile. You must specify this as a relative path at the top of the Puppetfile, before you list any modules.

To change the installation paths for only certain modules or data, declare those content sources as Git repositories and set the `install_path` option. This option overrides the `moduledir` directive. See the related topic about how to declare content as a Git repo for instructions.
Add the `moduledir` directive at the top of the Puppetfile, specifying your module installation directory relative to the location of the Puppetfile.

```
moduledir 'thirdparty'
```

### Declare Forge modules in the Puppetfile

Declare Forge modules in your Puppetfile, specifying the version and whether or not code management keeps the module updated.

Specify modules by their full name. You can specify the most recent version of a module, with or without updates, or you can specify a specific version of a module.

**Note:** Some existing Puppetfiles contain a `forge` setting that provides legacy compatibility with `librarian-puppet`. This setting is non-operational for Code Manager and r10k. To configure how Forge modules are downloaded, specify `forge_settings` in Hiera instead. See the topics about configuring the Forge settings for Code Manager or r10k for details.

In your Puppetfile, specify the modules to install with the `mod` directive. For each module, pass the module name as a string, and optionally, specify what version of the module you want to track.

If you specify no options, code management installs the latest version and keeps the module at that version. To keep the module updated, specify `:latest`. To install a specific version of the module and keep it at that version, specify the version number as a string.

```
mod 'puppetlabs/apache'
mod 'puppetlabs/ntp', :latest
mod 'puppetlabs/stdlib', '0.10.0'
```

This example:
- Installs the latest version of the apache module, but does not update it.
- Installs the latest version of the ntp module, and updates it when environments are deployed.
- Installs version 0.10.0 of the stdlib module, and does not update it.

### Declare Git repositories in the Puppetfile

List the modules, data, or other non-module content that you want to install from a Git repository.

To specify any environment content as a Git repository, use the `mod` directive with the `:git` option. This is useful for modules you don't get from the Forge, such as your own modules, as well as data or other non-module content.

To install content and keep it updated to the master branch, declare the content name and specify the repository with the `:git` directive. Optionally, specify an `:install_path` for the content.

```
mod 'apache',
  :git => 'https://github.com/puppetlabs/puppetlabs-apache'
mod 'site_data',
  :git => 'git@git.example.com:site_data.git',
  :install_path => 'hieradata'
```

This example installs the apache module and keeps that module updated with the master branch of the listed repository. It also installs site data content from a Git repository into the environment's `.hieradata/site_data` subdirectory.

**Note:** Content is installed in the modules directory and treated as a module, unless you use the `:install_path` option. Use this option with non-module content to keep your data separate from your modules.
Specify installation paths for repositories
You can set individual installation paths for any of the repositories that you declare in the Puppetfile.

The :install_path option allows you to separate non-module content in your directory structure or to set specific installation paths for individual modules. When you set this option for a specific repository, it overrides the moduledir setting.

To install the content into a subdirectory in the environment, specify the directory with the install_path option. To install into the root of the environment, specify an empty value.

    mod 'site_data_1',
       :git => 'git@git.example.com:site_data_1.git',
       :install_path => 'hieradata'
    mod 'site_data_2',
       :git => 'git@git.example.com:site_data_2.git',
       :install_path => ''

This example installs site data content from the site_data_1 repository into ./hieradata/site_data and content from site_data_2 into ./site_data subdirectory.

Declare module or data content with SSH private key authentication
To declare content protected by SSH private keys, declare the content as a repository, and then configure the private key setting in your code management tool.

1. Declare your repository content, specifying the Git repo by the SSH URL.

    mod 'myco/privatemod',
       :git => 'git@git.example.com:myco/privatemod.git'

2. Configure the correct private key by setting Code Manager or r10k parameters in Hiera:
   - To set a key for all Git operations, use the private key setting under git-settings.
   - To set a private key for an individual remote, set the private key in the repositories hash in git-settings for each specific remote.

Keep repository content at a specific version
The Puppetfile can maintain repository content at a specific version.

To specify a particular repository version, declare the version you want to track with your choice of the following options. Setting one of these options maintains the repository at that version and deploys any updates you make to that particular version.

- ref: Specifies the Git reference to check out. This option can reference either a tag, a commit, or a branch.
- tag: Specifies the repo by a certain tag value.
- commit: Specifies the repo by a certain commit.
- branch: Specifies a certain branch of the repo.
- default_branch: Specifies a default branch to use for deployment if the specified ref, tag, commit, or branch cannot be deployed. You must also specify one of the other version options. This is useful if you are tracking a relative branch of the control repo.

In the Puppetfile, declare the content, specifying the repository and version you want to track.

To install puppetlabs/apache and specify the '0.9.0' tag, use the tag option.

    mod 'apache',
       :git => 'https://github.com/puppetlabs/puppetlabs-apache',
       :tag => '0.9.0'
To install `puppetlabs/apache` and use the `branch` option to track the 'proxy_match' branch.

```ruby
mod 'apache',
  :git  => 'https://github.com/puppetlabs/puppetlabs-apache',
  :branch => 'proxy_match'
```

To install `puppetlabs/apache` and use the `commit` option to track the '8df51aa' commit.

```ruby
mod 'apache',
  :git  => 'https://github.com/puppetlabs/puppetlabs-apache',
  :commit => '8df51aa'
```

**Declare content from a relative control repo branch**

The `branch` option also has a special `:control_branch` option, which allows you to deploy content from a control repo branch relative to the location of the Puppetfile.

Normally, `branch` tracks a specific named branch of a repo, such as testing. If you set it to `:control_branch`, it instead tracks whatever control repo branch the Puppetfile is in. For example, if your Puppetfile is in the production branch, content from the production branch is deployed; if a duplicate Puppetfile is located in testing, content from testing is deployed. This means that as you create new branches, you don't have to edit the inherited Puppetfile as extensively.

To track a branch within the control repo, declare the content with the `:branch` option set to `:control_branch`.

```ruby
mod 'hieradata',
  :git  => 'git@git.example.com:organization/hieradata.git',
  :branch => :control_branch
```

**Set a default branch for content deployment**

Set a `default_branch` option to specify what branch code management deploys content from if the given option for your repository cannot be deployed.

If you specified a `ref`, `tag`, `commit`, or `branch` option for your repository, and it cannot be resolved and deployed, code management can instead deploy the `default_branch`. This is mostly useful when you set `branch` to the `:control_branch` value.

If your specified content cannot be resolved and you have not set a default branch, or if the default branch cannot be resolved, code management logs an error and does not deploy or update the content.

In the Puppetfile, in the content declaration, set the `default_branch` option to the branch you want to deploy if your specified option fails.

```ruby
# Track control branch and fall-back to master if no matching branch.
mod 'hieradata',
  :git  => 'git@git.example.com:organization/hieradata.git',
  :branch => :control_branch,
  :default_branch => 'master'
```
Managing code with Code Manager

Code Manager automates the management and deployment of your Puppet code. Push code updates to your source control repo, and then Puppet syncs the code to your masters, so that all your servers start running the new code at the same time, without interrupting agent runs.

- **How Code Manager works** on page 588
  Code Manager uses r10k and the file sync service to stage, commit, and sync your code, automatically managing your environments and modules.

- **Configuring Code Manager** on page 589
  To configure Code Manager, enable it in Puppet Enterprise (PE), set up authentication, and test the communication between the control repo and Code Manager.

- **Customize Code Manager configuration in Hiera** on page 594
  To customize your Code Manager configuration, set parameters with Hiera.

- **Triggering Code Manager on the command line** on page 601
  The `puppet-code` command allows you to trigger Code Manager from the command line to deploy your environments.

- **Triggering Code Manager with a webhook** on page 606
  To deploy your code, you can trigger Code Manager by hitting a web endpoint, either through a webhook or a custom script. The webhook is the simplest way to trigger Code Manager.

- **Triggering Code Manager with custom scripts** on page 607
  Custom scripts are a good way to trigger deployments if you have requirements such as existing continuous integration systems, privately hosted Git repos, or custom notifications.

- **Troubleshooting Code Manager** on page 609
  Code Manager requires coordination between multiple components, including r10k and the file sync service. If you have issues with Code Manager, check that these components are functioning.

- **Code Manager API** on page 612
  Use Code Manager endpoints to deploy code and query environment deployment status on your masters without direct shell access.

**How Code Manager works**

Code Manager uses r10k and the file sync service to stage, commit, and sync your code, automatically managing your environments and modules.

First, create a control repository with branches for each environment that you want to create (such as production, development, or testing). Create a Puppetfile for each of your environments, specifying exactly which modules to install in each environment. This allows Code Manager to create directory environments, based on the branches you've set up. When you push code to your control repo, you trigger Code Manager to pull that new code into a staging code directory (`/etc/puppetlabs/code-staging`). File sync then picks up those changes, pauses Puppet Server to avoid conflicts, and then synces the new code to the live code directories on your masters.

For more information about using environments in Puppet, see About Environments.

**Understanding file sync and the staging directory**

To sync your code across multiple masters and to make sure that code stays consistent, Code Manager relies on file sync and two different code directories: the staging directory and the live code directory.

Without Code Manager or file sync, Puppet code lives in the codedir, or live code directory, at `/etc/puppetlabs/code`. But the file sync service looks for code in a code staging directory (`/etc/puppetlabs/code-staging`), and then synces that to the live codedir.

Code Manager moves new code from source control into the staging directory, and then file sync moves it into the live code directory. This means you no longer write code to the codedir; if you do, the next time Code Manager deploys code from source control, it overwrites your changes.

For more detailed information about how file sync works, see the related topic about file sync.

© 2020 Puppet, Inc.
CAUTION:

Don't directly modify code in the staging directory. Code Manager overwrites it with updates from the control repo. Similarly, don't modify code in the live code directory, because file sync overwrites that with code from the staging directory.

Related information

About file sync on page 635

File sync helps Code Manager keep your Puppet code synchronized across multiple masters.

Environment isolation metadata and Code Manager

Both your live and staging code directories contain metadata files that are generated by file sync to provide environment isolation for your resource types.

These files, which have a .pp extension, ensure that each environment uses the correct version of the resource type. Do not delete or modify these files. Do not use expressions from these files in regular manifests.

These files are generated as Code Manager deploys new code in your environments. If you are new to Code Manager, these files are generated when you first deploy your environments. If you already use Code Manager, the files are generated as you make and deploy changes to your existing environments.

For more details about these files and how they isolate resource types in multiple environments, see environment isolation.

Moving from r10k to Code Manager

Switching from r10k to Code Manager can improve automation of your code management and deployments, but some r10k users might not be ready to switch yet.

Code Manager uses r10k in the background to improve automation of your code management and deployment. However, switching to Code Manager means you can no longer use r10k manually. Because of this, some r10k users might not want to move to Code Manager yet. Specifically, be aware of the following restrictions:

• If you use Code Manager, you cannot deploy code manually with r10k. If you depend on the ability to deploy modules directly from r10k, using the r10k deploy module command, continue to use your current r10k workflow.

• Code Manager must deploy all control repos to the same directory. If you are using r10k to deploy control repos to different directories, continue to use your current r10k workflow.

• Code Manager does not support system .SSH configuration or other shellgit options.

• Code Manager does not support post-deploy scripts.

If you rely on any of the above configurations, or any other r10k configuration that Code Manager doesn't yet support, continue to use your current r10k workflow. If you are using a custom script to deploy code, carefully assess whether Code Manager meets your needs.

Related information

Managing code with r10k on page 623

r10k is a code management tool that allows you to manage your environment configurations (such as production, testing, and development) in a source control repository.

Configuring Code Manager

To configure Code Manager, enable it in Puppet Enterprise (PE), set up authentication, and test the communication between the control repo and Code Manager.

When you finished configuration, you're ready to deploy environments with Code Manager.

You can enable and configure Code Manager either during or after r10k installation.

To enable Code Manager after a new installation or in an existing PE installation, set Code Manager parameters in the console. You can also configure Code Manager during a fresh PE installation, but only during a text-mode installation.
1. Enable and configure Code Manager, after installation or upgrade, by setting parameters in the master profile class in the PE console. Alternatively, enable during a fresh installation, by setting parameters in `pe.conf`.

2. Test your control repo.

3. Set up authentication for Code Manager.

4. Test Code Manager.

**Upgrading from r10k to Code Manager**
If you are upgrading from r10k to Code Manager, you must first disable your old r10k installation.

If you are upgrading from r10k to Code Manager, check the following before enabling Code Manager:

- If you used r10k prior to PE 2015.3, you might have configured r10k in the console using the `pe_r10k` class. If so, you must remove the `pe_r10k` class in the console **before** configuring Code Manager.

- If you used any previous versions of r10k, disable any tools that might automatically run it. Most commonly, this is the `zack-r10k` module. Code Manager cannot install or update code properly if other tools are running r10k.

When you start using Code Manager, it runs r10k in the background. You can no longer directly interact with r10k or use the `zack-r10k` module.

**Enable Code Manager**
Enabling Code Manager connects your master to your Git repository.

**Before you begin**
You must have an SSH key that:

- Does not have a passphrase.

- Is owned by the `pe-puppet` user.

- Is located on the master in a directory that the `pe-puppet` user has permission to view. We recommend `/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa`

1. In the console, set the following parameters in the `puppet_enterprise::profile::master` class in the PE Master node group.

   - `code_manager_auto_configure` to `true`: This enables and configures both Code Manager and file sync.

   - `r10k_remote`: This is the location of your control repository, as accessed by SSH. Enter a string that is a valid SSH URL for your Git control repository. For example: "git@YOUR.GIT.SERVER.COM::puppet/control.git".

     **Note**: Some Git providers, such as Bitbucket, might have additional requirements for enabling SSH access. See your provider's documentation for information.

   - `r10k_private_key`: Enter a string specifying the path to the SSH private key that permits the user to access your Git repositories.

2. Run Puppet on your master and all compilers.

   If you run Puppet for your master and all compilers at the same time, such as with **Run Puppet** in the console, you might see errors like this your compilers' logs:

   ```
   2015-11-20 08:14:38,308 ERROR [clojure-agent-send-off-pool-0]
   java.net.ConnectException: Connection refused
   ```

   You can ignore these errors. They occur because Puppet Server is restarting while the compilers are trying to poll for new code. These errors generally stop as soon as the Puppet Server on the master has finished restarting.

3. Set up authentication.
Set up authentication for Code Manager
To securely deploy environments, Code Manager needs an authentication token for both authentication and authorization.

Before you begin
If you would like to use PE client tools, configure these now. PE client tools let you access PE services from a workstation that is not necessarily managed by Puppet. They come pre-installed on your master, but you need to configure them by creating a configuration file. See Configuring PE client tools for more information.

To generate a token for Code Manager, first assign a user to the deployment role, and then request an authentication token.

Related information
Configure puppet-access on page 208
The puppet-access command allows users to generate and manage authentication tokens from the command line of any workstation (Puppet-managed or not), without the need to SSH into the Puppet master. Ensure puppet-access is configured correctly before using it to generate authentication tokens.

Assign a user to the deployment role
To request an authentication token, you must first assign a user the correct permissions with role-based access control (RBAC).

1. In the console, create a deployment user. We recommend that you create a dedicated deployment user for Code Manager use.
2. Add the deployment user to the Code Deployers role. This role is automatically created on install, with default permissions for code deployment and token lifetime management.
3. Create a password by clicking Generate Password.

Request the authentication token.

Related information
Add a user to a user role on page 200
When you add users to a role, the user gains the permissions that are applied to that role. A user can't do anything in PE until they have been assigned to a role.

Assign a user group to a user role on page 207
After you've imported a group, you can assign it a user role, which gives each group member the permissions associated with that role. You can add user groups to existing roles, or you can create a new role, and then add the group to the new role.

Request an authentication token for deployments
Request an authentication token for the deployment user to enable secure deployment of your code.

By default, authentication tokens have a one-hour lifetime. With the Override default expiry permission set, you can change the lifetime of the token to a duration better suited for a long-running, automated process.

Generate the authentication token using the puppet-access command.

1. From the command line on the master, run puppet-access login --lifetime 180d. This command both requests the token and sets the token lifetime to 180 days.
   Tip: You can add flags to the request specifying additional settings such as the token file's location or the URL for your RBAC API. See Configuration file settings for puppet-access.
2. Enter the username and password of the deployment user when prompted.

The generated token is stored in a file for later use. The default location for storing the token is ~/.puppetlabs/token. To view the token, run puppet-access show.

Test the connection to the control repo.

Related information
Setting a token-specific lifetime on page 212

© 2020 Puppet, Inc.
Tokens have a default lifetime of one hour, but you can set a different lifetime for your token when you generate it. This allows you to keep one token for multiple sessions.

*Generate a token for use by a service* on page 211

If you need to generate a token for use by a service and the token doesn’t need to be saved, use the `--print` option.

**Test the control repo**

To make sure that Code Manager can connect to the control repo, test the connection to the repository.

From the command line, run `puppet-code deploy --dry-run`.

- If the control repo is set up properly, this command fetches and displays the number of environments in the control repo.
- If an environment is not set up properly or causes an error, it does not appear in the returned list. Check the Puppet Server log for details about the errors.

**Test Code Manager**

To test whether Code Manager deploys your environments correctly, trigger a single environment deployment on the command line.

**Deploy a single environment**

Test Code Manager by deploying a single test environment.

This deploys the test environment, and then returns deployment results with the SHA (a checksum for the content stored) for the control repo commit.

From the command line, deploy one environment by running `puppet-code deploy my_test_environment --wait`.

Check to make sure the environment was deployed. If so, you’ve set up Code Manager correctly.

If the deployment does not work as you expect, check over the configuration steps, or refer to the troubleshooting guide for help.

After Code Manager is fully enabled and configured, you can trigger it to deploy your environments.

There are several ways to trigger deployments, depending on your needs.

- Manually, on the command line.
- Automatically, with a webhook.
- Automatically, with a custom script that hits the deploys endpoint.

**Deploy code without blocking requests to Puppet Server**

When compiling code, Puppet Server typically blocks requests, including catalog compilation, until file sync is done updating the Puppet code directory. You can enable lockless deploys so the file sync client updates code into versioned code directories instead of blocking requests and overwriting the live code directory.

With lockless deploys enabled, each new deploy writes code to versioned directories at `/opt/puppetlabs/server/data/puppetserver/filesync/client/versioned-dirs/puppet-code/`. The standard code directory, `/etc/puppetlabs/code` is reconfigured to `/etc/puppetlabs/puppetserver/code`, which points via symlink to the most recent versioned code directory. If you disable lockless deploys after enabling it, your code directory is moved back to the default location.

To conserve disk space, code written to version directories is optimized to reduce duplication, and directories older than the latest and its predecessor are cleaned up after 30 minutes. If you deploy code very frequently, you might prefer to decrease the `versioned-dirs-ttl` setting, which is specified, in minutes, in `file-sync.conf` within each repository.

**Note:** Lockless deploys are an experimental feature which might experience breaking changes in future releases. We recommend testing the feature in a non-production environment before enabling it in production.

1. In the console, click **Node groups** and select the **PE Master** node group.
2. On the **Classes** tab, in the `puppet_enterprise::profile::master` class, set `versioned_deploys = true` and click **Add parameter**.
3. Commit changes.

4. Run Puppet on your master and all compilers: `puppet agent -t`

The next time you deploy code, your code directory is reconfigured from `/etc/puppetlabs/code` to `/etc/puppetlabs/puppetserver/code`, and versioned code directories are added at `/opt/puppetlabs/server/data/puppetserver/filesync/client/versioned-dirs/puppet-code/`.

**System requirements for lockless deploys**

Enabling *lockless deploys* increases the disk storage required on your master and compilers, because code is written to multiple versioned directories, instead of a single live code directory. Follow these guidelines for estimating your required system capacity.

You can roughly estimate your required disk storage with this equation:

\[
\text{Required disk storage} = \frac{\text{Size of typical environment} \times \text{Number of active environments}}{1024}\]

For example, if your typical environment, when deployed, is 200 MB on disk, and you have 25 active environments, your disk storage calculation is \(200 \text{ MB} \times 25 = 5,000 \text{ MB or 5 GB.}\)

The number of times you deploy a given environment each day also impacts your disk use. Deploying multiple versions of the same environment uses approximately 25 percent more disk space than deploying multiple unique environments. To estimate the *additional* disk storage required for deploying environments multiple times a day, use this equation:

\[
\text{Additional disk storage} = \frac{\text{Size of typical environment} \times .25 \times\text{Number of environments deployed multiple times per day} \times\text{Number of deployments per day}}{1024}\]

Expanding on the previous example, if 10 of your active environments are deployed up to 10 times per day, your disk storage calculation is \(50 \text{ MB} \times 10 \times 10 = 5,000 \text{ MB or an additional 5 GB of disk space.}\) In total then, you need 10 GB available for your master and each compiler.

**Note:** If you're using the Continuous Delivery for PE impact analysis tool, you might need additional disk space beyond these estimates in order to accommodate the short-lived environments created during impact analysis.

**Code Manager console settings**

After Code Manager is configured, you can adjust some settings in the master profile in the console.

These options are required for Code Manager to work, unless otherwise noted.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>code_manager_auto_configure</td>
<td>Specifies whether to autoconfigure Code Manager.</td>
<td><code>true</code></td>
</tr>
<tr>
<td>r10k_remote</td>
<td>The location, as a valid URL, for your Git control repository.</td>
<td><code>git@&lt;YOUR.GIT.SERVER.COM&gt;:puppet/control.git</code></td>
</tr>
<tr>
<td>r10k_private_key</td>
<td>The path to the file containing the private key used to access all Git repositories. Required when using the SSH protocol; optional in all other cases.</td>
<td><code>/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa</code></td>
</tr>
<tr>
<td>r10k_proxy</td>
<td>Optional proxy used by r10k when accessing the Forge. If empty, no proxy settings are used.</td>
<td><code>http://proxy.example.com:3128</code></td>
</tr>
<tr>
<td>versioned_deploys</td>
<td>Optional setting that specifies whether code is updated in versioned code directories instead of blocking requests and overwriting the live code directory.</td>
<td><code>true</code></td>
</tr>
</tbody>
</table>
To further customize your Code Manager configuration with Hiera, see the related topic about customizing your configuration.

**Customize Code Manager configuration in Hiera**

To customize your Code Manager configuration, set parameters with Hiera.

Add Code Manager parameters in the `puppet_enterprise::master::code_manager` class with Hiera.

**Important:**

Do not edit the Code Manager configuration file manually. Puppet manages this configuration file automatically and undoes any manual changes you make.

**Related information**

[Configure settings with Hiera](#) on page 152

Hiera is a hierarchy-based method of configuration management that relies on a “defaults, with overrides” system. When you add a parameter or setting to your Hiera data, Hiera searches through the data in the order it was written to find the value you want to change. Once found, it overrides the default value with the new parameter or setting. You can use Hiera to manage your PE configuration settings.

**Add Code Manager parameters in Hiera**

To customize your Code Manager configuration, add parameters to your control repository hierarchy in the `data/common.yaml` file.

1. Add the parameter to `data/common.yaml` in the format:
   ```yaml
   puppet_enterprise::master::code_manager::<parameter>
   ```
   ```yaml
   puppet_enterprise::master::code_manager::deploy_pool_size: 4
   puppet_enterprise::master::code_manager::timeouts_deploy: 300
   ```
   The first parameter in this example increases the size of the default worker pool, and the second reduces the maximum time allowed for deploying a single environment.

2. Run Puppet on the master to apply changes.

**Configuring post-environment hooks**

Configure post-environment hooks to trigger custom actions after your environment deployment.

To configure list of hooks to run after an environment has been deployed, specify the Code Manager `post_environment_hook` setting in Hiera.

This parameter accepts an array of hashes, with the following keys:

- `url`
- `use-client-ssl`

For example, to enable Code Manager to update classes in the console after deploying code to your environments.

```yaml
puppet_enterprise::master::code_manager::post_environment_hooks:
    use-client-ssl: true
```

**url**

This setting specifies an HTTP URL to send a request to, with the result of the environment deploy. The URL receives a POST with a JSON body with the structure:

```json
{
    "deploy-signature":"d482f8d3adc76b5197306c5d4c8aa32aa8315694b",
    "file-sync":{
        "environment-commit":"6939889b679f6f1449545c44f26aa06174d25c21",
    }
}
```
use-client-ssl

Specifies whether the client SSL configuration is used for HTTPS connections. If the hook destination is a server using the Puppet CA, set this to `true`; otherwise, set it to `false`. Defaults to `false`.

**Configuring garbage collection**

By default, Code Manager retains environment deployments in memory for one hour, but you can adjust this by configuring garbage collection.

To configure the frequency of Code Manager garbage collection, specify the `deploy_ttl` parameter in Hiera. By default, deployments are kept for one hour.

Specify the time as a string using any of the following suffixes:

- **d** - days
- **h** - hours
- **m** - minutes
- **s** - seconds
- **ms** - milliseconds

For example, a value of `30d` would configure Code Manager to keep the deployment in memory for 30 days, and a value of `48h` would maintain the deployment in memory for 48 hours.

If the value of `deploy-ttl` is less than the combined values of `timeouts_fetch`, `timeouts_sync`, and `timeouts_deploy`, all completed deployments are retained indefinitely, which might significantly slow the performance of Code Manager over time.

**Configuring Forge settings**

To configure how Code Manager downloads modules from the Forge, specify `forge_settings` in Hiera.

This parameter configures where Forge modules should be installed from, and sets a proxy for all Forge interactions.

The `forge_settings` parameter accepts a hash with the following values:

- **baseurl**
- **proxy**

**baseurl**

Indicates where Forge modules should be installed from. Defaults to `https://forgeapi.puppetlabs.com`.

```
puppet_enterprise::master::code_manager::forge_settings:
  baseurl: 'https://private-forge.mysite'
```

**proxy**

Sets the proxy for all Forge interactions.

This setting overrides the global `proxy` setting on Forge operations only. You can set an unauthenticated proxy or an authenticated proxy with either Basic or Digest authentication. See the global `proxy` setting for more information and examples.

```
proxy: 'http://proxy.example.com:3128'
```
**Configuring Git settings**

To configure Code Manager to use a private key, a proxy, or multiple repositories with Git, specify the `git_settings` parameter.

The `git_settings` parameter accepts a hash of the following settings:

- `private-key`
- `proxy`
- `repositories`

**Note:** You cannot use the `git_settings` hash with the default Code Manager settings for `r10k_private_key`. To avoid errors, remove the `r10k_private_key` from the `puppet-enterprise::profile::master` class.

**private-key**

Specifies the file containing the default private key used to access control repositories, such as `/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa`. This file must have read permissions for the `pe-puppet` user. The SSH key cannot require a password. This setting is required, but by default, the value is supplied by the master profile in the console.

**proxy**

Sets a proxy specifically for Git operations that use an HTTP(S) transport.

This setting overrides the global `proxy` setting on Git operations only. You can set an unauthenticated proxy or an authenticated proxy with either Basic or Digest authentication. To set a proxy for a specific Git repository only, set `proxy` in the `repositories` subsetting of `git_settings`. See the global `proxy` setting for more information and examples.

```
proxy: 'http://proxy.example.com:3128'
```

**repositories**

Specifies a list of repositories and their respective private keys. Use this setting if you want to use multiple control repos.

To use multiple control repos, the `sources` setting and the `repositories` setting must match. Accepts the following settings:

- `remote`: The repository to which these settings apply.
- `private-key`: The file containing the private key to use for this repository. This file must have read permissions for the `pe-puppet` user.
- `proxy`: The proxy setting allows you to set or override the global proxy setting for a single, specific repository. See the global `proxy` setting for more information and examples.

The `repositories` setting accepts a hash in the following format:

```
repositories:
- remote: "jfkennedy@gitserver.puppetlabs.net:repositories/repo_one.git"
  private-key: "/test_keys/jfkennedy"
- remote: "whtaft@gitserver.puppetlabs.net:repositories/repo_two.git"
  private-key: "/test_keys/whtaft"
- remote: "https://git.example.com/git_repos/environments.git"
  proxy: "https://proxy.example.com:3128"
```
**Configuring proxies**
To configure proxy servers, use the proxy setting. You can set a global proxy for all HTTP(S) operations, for all Git or Forge operations, or for a specific Git repository only.

**proxy**
To set a proxy for all operations occurring over an HTTP(S) transport, set the global `proxy` setting. You can also set an authenticated proxy with either Basic or Digest authentication.

To override this setting for Git or Forge operations only, set the `proxy` subsetting under the `git_settings` or `forge_settings` parameters. To override for a specific Git repository, set a proxy in the `repositories` list of `git_settings`. To override this setting with no proxy for Git, Forge, or a particular repository, set that specific `proxy` setting to an empty string.

In this example, the first proxy is set up without authentication, and the second proxy uses authentication:

```plaintext
proxy: 'http://proxy.example.com:3128'
proxy: 'http://user:password@proxy.example.com:3128'
```

**Configuring sources**
If you are managing more than one repository with Code Manager, specify a map of your source repositories.

Use the `source` parameter to specify a map of sources. Configure this setting if you are managing more than just Puppet environments, such as when you are also managing Hiera data in its own control repository.

To use multiple control repos, the `sources` setting and the `repositories` setting must match.

If `sources` is set, you cannot use the global `remote` setting. If you are using multiple sources, use the prefix option to prevent collisions.

The `sources` setting accepts a hash with the following subsettings:

- `remote`
- `prefix`

```plaintext
myorg:
  remote: "git://git-server.site/myorg/main-modules"
  prefix: true
mysource:
  remote: "git://git-server.site/mysource/main-modules"
  prefix: "testing"
```

**remote**
Specifies the location from which you fetch the source repository. The remote must be able to be fetched without any interactive input. That is, you cannot be prompted for usernames or passwords in order to fetch the remote.

Accepts a string that is any valid URL that r10k can clone, such as `git://git-server.site/my-org/main-modules`.

**prefix**
Specifies a string to prefix to environment names. Alternatively, if `prefix` is set to `true`, the source's name is used. This prevents collisions when multiple sources are deployed into the same directory.

For example, with two "main-modules" environments set up in the same base directory, the prefix setting differentiates the environments: the first is named "myorg-main-modules", and the second is "testing-main-modules".

```plaintext
myorg:
  remote: "git://git-server.site/myorg/main-modules"
  prefix: true
mysource:
```
remote: "git://git-server.site/mysource/main-modules"
prefix: "testing"

**Code Manager parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Value</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote</td>
<td>The location of the Git control repository. Either the remote or sources parameters must be specified. If remote is already specified in the master profile, that value is used here. If both the sources and remote keys are specified, the sources key overrides remote.</td>
<td>A string that is a valid SSH URL for your Git remote.</td>
<td>No default.</td>
</tr>
<tr>
<td>authenticate_webhook</td>
<td>Turns on RBAC authentication for the /v1/webhook endpoint.</td>
<td>Boolean.</td>
<td>true</td>
</tr>
<tr>
<td>cachedir</td>
<td>The path to the location where Code Manager caches Git repositories.</td>
<td>A valid file path.</td>

---

### Triggering Code Manager on the command line

The `puppet-code` command allows you to trigger Code Manager from the command line to deploy your environments.

#### Installing and configuring puppet-code

PE automatically installs and configures the `puppet-code` command on your masters as part of the included PE client tools package. You can also set up `puppet-code` on an agent node or on a workstation, customize configuration for different users, or change the configuration settings.

The global configuration settings for Linux and macOS systems are in a JSON file at `/etc/puppetlabs/client-tools/puppet-code.conf`. The default configuration file looks something like:

```json
{
    "cacert": "/etc/puppetlabs/puppet/ssl/certs/ca.pem",
    "token-file": "~/.puppetlabs/token",
    "service-url": "https://<PUPPET MASTER HOSTNAME>:8170/code-manager"
}
```

**Important:**

On a PE-managed machine, Puppet manages this file for you. Do not manually edit this file, because Puppet overwrites your new values the next time it runs.

Additionally, you can set up `puppet-code` on an agent node or on a workstation not managed by PE. And on any machine, you can set up user-specific config files. For instructions, see the related topic about advanced configuration of `puppet-code`.

You can also override existing configuration settings on a case-by-case basis on the command line. When you deploy environments with the `puppet-code deploy` command, you can specify either an alternative config file or particular config settings directly in the command. For examples, see the related topic about deploying environments with `puppet code`.

#### Windows paths

The global `puppet-code` configuration file on Windows systems is located at `C:\ProgramData\PuppetLabs\client-tools\puppet-code.conf`.

The default configuration file looks something like:

```json
{
    "cacert": "C:\ProgramData\PuppetLabs\puppet\etc\ssl\certs\ca.pem",
    "token-file": "C:\Users\<username>\.puppetlabs\token",
    "service-url": "https://<PUPPET MASTER HOSTNAME>:8170/code-manager"
}
```
Configuration precedence and puppet-code
There are several ways to configure puppet-code, but some configuration methods take precedence over others.

If no other configuration is specified, puppet-code uses the settings in the global configuration file. User-specific configuration files override the global configuration file.

If you specify a configuration file on the command line, Puppet temporarily uses that configuration file only and does not read the global or user-specific config files at all.

Finally, if you specify individual configuration options directly on the command line, those options temporarily take precedence over any configuration file settings.

Deploying environments with puppet-code
To deploy environments with the puppet-code command, use the deploy action, either with the name of a single environment or with the --all flag.

The deploy action deploys the environments, but returns only deployment queuing results by default. To view the results of the deployment itself, add the --wait flag.

The --wait flag deploys the specified environments, waits for file sync to complete code deployment to the live code directory and all compilers, and then returns results. In deployments that are geographically dispersed or have a large quantity of environments, completing code deployment can take up to several minutes.

The resulting message includes the deployment signature, which is the commit SHA of the control repo used to deploy the environment. The output also includes two other SHAs that indicate that file sync is aware that the environment has been newly deployed to the code staging directory.

To temporarily override default, global, and user-specific configuration settings, specify the following configuration options on the command line:

- --cacert
- --token-file,-t
- --service-url

Alternately, you can specify a custom puppet-code.conf configuration file by using the --config-file option.

Running puppet-code on Windows
If you're running these commands from a managed or non-managed Windows workstation, you must specify the full path to the command.

C:\Program Files\Puppet Labs\Client\bin\puppet code deploy mytestenvironment --wait

Deploy environments on the command line
To deploy environments, use the puppet-code deploy command, specifying the environments to deploy.

To deploy environments, on the command line, run puppet-code deploy, specifying the environment.

Specify the environment by name. To deploy all environments, use the --all flag.

Optionally, you can specify the --wait flag to return results after the deployment is finished. Without the --wait flag, the command returns only queuing results.

puppet-code deploy myenvironment --wait
puppet-code deploy --all --wait

Both of these commands deploy the specified environments, and then return deployment results with a control repo commit SHA for each environment.

Related information
Reference: puppet-code command on page 604

© 2020 Puppet, Inc.
The `puppet-code` command accepts options, actions, and deploy action options.

**Deploy with a custom configuration file**
You can deploy environments with a custom configuration file that you specify on the command line.

To deploy all environments using the configuration settings in a specified config file, run the command `puppet-code deploy` command with a `--config-file` flag specifying the location of the config file.

```
puppet-code --config-file ~/.puppetlabs/myconfigfile/puppet code.conf deploy --all
```

**Deploy with command-line configuration settings**
You can override an existing configuration setting on a per-use basis by specifying that setting on the command line.

Specify the setting, which is used on this deployment only, on the command line.

```
puppet-code --service-url "https://puppet.example.com:8170/code-manager" deploy mytestenvironment
```

This example deploys 'mytestenvironment' using global or user-specific config settings (if set), except for `--service-url`, for which it uses the value specified on the command line ("https://puppet.example.com:8170/code-manager").

**Advanced puppet-code configuration**
You can set up the `puppet-code` command on an agent node or on a workstation not managed by PE. And on any machine, you can set up user-specific config files.

You can set up the `puppet-code` command on an agent node or on a workstation not managed by PE. And on any machine, you can set up user-specific config files.

The `puppet-code.conf` file is a JSON configuration file for the `puppet-code` command. For Linux or Mac OS X operating systems, it looks something like:

```
{
    "cacert": "/etc/puppetlabs/puppet/ssl/certs/ca.pem",
    "token-file": "~/.puppetlabs/token",
    "service-url": "https://<PUPPET MASTER HOSTNAME>:8170/code-manager"
}
```

For Windows systems, use the entire Windows path, such as:

```
{
    "cacert": "C:\ProgramData\PuppetLabs\puppet\etc\ssl\certs\ca.pem",
    "token-file": "C:\Users\<username>\.puppetlabs\token",
    "service-url": "https://<PUPPET MASTER HOSTNAME>:8170/code-manager"
}
```

**Related information**
- Installing PE client tools on page 129
- PE client tools are a set of command line tools that let you access Puppet Enterprise services from a workstation that might or might not be managed by Puppet.

**Configure puppet-code on agents and workstations**
To use `puppet-code` on an agent node or on a workstation that is not managed by PE, install the client tools package and configure `puppet-code` on that machine.

**Before you begin**
Download and install the client tools package. See the client tools documentation for instructions.
Create a config file called `puppet-code.conf` in the client tools directory.

- For Linux and Mac OS X systems, the default client tools directory is `/etc/puppetlabs/client-tools`
- For Windows systems, the default client tools directory is `C:\ProgramData\PuppetLabs\client-tools`

**Configure puppet-code for different users**

On any machine, whether it is a master, an agent, or a workstation not managed by PE, you can set up specific puppet-code configurations for specific users.

**Before you begin**

If PE is not installed on the workstation you are configuring, see instructions for configuring puppet-code on agents and workstations.

1. Create a `puppet-code.conf` file in the user's client tools directory.
   - For Linux or Mac OS X systems, place the file in the user's `~/.puppetlabs/client-tools/`
   - For Windows systems, place the file in the default user config file location: `C:\Users\<username>\.puppetlabs\ssl\certs\ca.pem`

2. In the user's `puppet-code.conf` file, specify the `cacert`, `token-file`, and `service-url` settings in JSON format.

**Reference: puppet-code command**

The puppet-code command accepts options, actions, and deploy action options.

Usage: `puppet-code [global options] <action> [action options]`

**Global puppet-code options**

Global options set the behavior of the puppet-code command on the command line.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

</tr>
</tbody>
</table>

**Triggering Code Manager with a webhook**

To deploy your code, you can trigger Code Manager by hitting a web endpoint, either through a webhook or a custom script. The webhook is the simplest way to trigger Code Manager.

Custom scripts are a good alternative if you have requirements such as existing continuous integration systems (including Continuous Delivery for Puppet Enterprise (PE)), privately hosted Git repos, or custom notifications. For information about writing a script to trigger Code Manager, see the related topic about creating custom scripts.

Code Manager supports webhooks for GitHub, Bitbucket Server (formerly Stash), Bitbucket, and Team Foundation Server. The webhook must only be used by the control repository. It can't be used by any other repository (for example, other internal component module repositories).

**Important:** Code Manager webhooks are not compatible with Continuous Delivery for PE. If your organization uses Continuous Delivery for PE, you must use a method other than webhooks to deploy environments.

**Creating a Code Manager webhook**
To set up the webhook to trigger environment deployments, you must create a custom URL, and then set up the webhook with your Git host.

**Creating a custom URL for the Code Manager webhook**
To trigger deployments with a webhook, you'll need a custom URL to enable communication between your Git host and Code Manager.

Code Manager supports webhooks for GitHub, Bitbucket Server (formerly Stash), Bitbucket, GitLab (Push events only), and Team Foundation Server (TFS). To use the GitHub webhook with the Puppet signed cert, disable SSL verification.

To create the custom URL for your webhook, use the following elements:

- The name of the Puppet master server (for example, `code-manager.example.com`).
- The Code Manager port (for example, 8170).
- The endpoint (`/code-manager/v1/webhook/`).
- Any relevant query parameters (for example, `type=github`).
- The complete authentication token you generated earlier (`token=<TOKEN>`), passed with the `token` query parameter.
For example, the URL for a GitHub webhook might look like this:

```
https://code-manager.example.com:8170/code-manager/v1/webhook?type=github&token=<TOKEN>
```

The URL for a version 5.4 or later Bitbucket Server webhook might look something like this:

```
```

With the complete token attached, a GitHub URL looks something like this:

```
https://code-manager.example.com:8170/code-manager/v1/webhook?type=github&token=0WJ4YPJVyQz26xm3X2i10ihb7MUa8l2CZWjxM3vt4mQ
```

**Code Manager webhook query parameters**
The following query parameters are permitted in the Code Manager webhook.

The `token` query is mandatory, unless you disable `authenticate_webhook` in the Code Manager configuration.

- **type**: Required. Specifies which type of post body to expect. Accepts:
  - `github`: GitHub
  - `gitlab`: GitLab
  - `bitbucket-server`: Bitbucket Server version 5.4 or later (formerly Stash)
  - `bitbucket`: Bitbucket
  - `tfs-git`: Team Foundation Server (resource version 1.0 is supported)
- **prefix**: Specifies a prefix for converting branch names to environments.
- **token**: Specifies the entire PE authorization token.

**Setting up the Code Manager webhook on your Git host**
Enter the custom URL you created for Code Manager into your Git server’s webhook form as the payload URL.

The content type for webhooks is JSON.

Exactly how you set up your webhook varies, depending on where your Git repos are hosted. For example, in your GitHub repo, click on **Settings > Webhooks & services** to enter the payload URL and enter `application/json` as the content type.

**Tip**: On Bitbucket Server, the server configuration menu has settings for both "hooks" and "webhooks." To set up Code Manager, use the webhooks configuration. For proper webhook function with Bitbucket Server, make sure you are using the Bitbucket Server 5.4 or later and the latest fix version of PE.

After you’ve set up your webhook, your Code Manager setup is complete. When you commit new code and push it to your control repo, the webhook triggers Code Manager, and your code is deployed.

**Testing and troubleshooting a Code Manager webhook**
To test and troubleshoot your webhook, review your Git host logs or check the Code Manager troubleshooting guide.

Each of the major repository hosting services (such as GitHub or Bitbucket) provides a way to review the logs for your webhook runs, so check their documentation for instructions.

For other issues, check the Code Manager troubleshooting for some common problems and troubleshooting tips.

**Triggering Code Manager with custom scripts**
Custom scripts are a good way to trigger deployments if you have requirements such as existing continuous integration systems, privately hosted Git repos, or custom notifications.

Alternatively, a webhook provides a simpler way to trigger deployments automatically.
To create a script that triggers Code Manager to deploy your environments, you can use either the `puppet-code` command or a `curl` statement that hits the endpoints. We recommend the `puppet-code` command.

Either way, after you have composed your script, you can trigger deployment of new code into your environments. Commit new code, push it to your control repo, and run your script to trigger Code Manager to deploy your code.

All of these instructions assume that you have enabled and configured Code Manager.

**Related information**

- **Request an authentication token for deployments** on page 58
  - Request an authentication token for the deployment user to enable secure deployment of your code.

- **Code Manager API** on page 612
  - Use Code Manager endpoints to deploy code and query environment deployment status on your masters without direct shell access.

**Deploying environments with the `puppet-code` command**

The `puppet-code` command allows you to trigger environment deployments from the command line. You can use this command in your custom scripts.

For example, to deploy all environments and then return deployment results with commit SHAs for each of your environments, incorporate this command into your script:

```
puppet-code deploy --all --wait
```

**Related information**

- **Triggering Code Manager on the command line** on page 601
  - The `puppet-code` command allows you to trigger Code Manager from the command line to deploy your environments.

**Deploying environments with a `curl` command**

To trigger Code Manager code deployments with a custom script, compose a `curl` command to hit the Code Manager/deploys endpoint.

To deploy environments with a `curl` command in your custom script, compose a `curl` command to hit the `/v1/deploys` endpoint.

Specify either the "deploy-all" key, to deploy all configured environments, or the "environments" key, to deploy a specified list of environments. By default, Code Manager returns queuing results immediately after accepting the deployment request.

If you prefer to get complete deployment results after Code Manager finishes processing the deployments, specify the optional "wait" key with your request. In deployments that are geographically dispersed or have a large number of environments, completing code deployment can take up to several minutes.

For complete information about Code Manager endpoints, request formats, and responses, see the Code Manager API documentation.

You must include a custom URL for Code Manager and a PE authentication token in any request to a Code Manager endpoint.

**Creating a custom URL for Code Manager scripts**

To trigger deployments with a `curl` command in a custom script, you’ll need a custom Code Manager URL. This URL is composed of:

- Your Puppet master server name (for example, `master.example.com`)
- The Code Manager port (for example, `8170`)
- The endpoint you want to hit (for example, `/code-manager/v1/deploys/`)
- The authentication token you generated earlier (token=<TOKEN>)
A typical URL for use with a `curl` command might look something like this:

https://master.example.com:8170/code-manager/v1/deploys&token=<TOKEN>

**Attaching an authentication token**

You must attach a PE authentication token to any request to Code Manager endpoints. You can either:

- Specify the path to the token with `puppet-access show` in the body of your request. For example:

  ```bash
  type_header='Content-Type: application/json'
  auth_header="X-Authentication: $(puppet-access show)"
  uri="https://$(puppet config print server):8170/code-manager/v1/deploys"
  data='{"environments": ["production"], "wait": true}"
  curl --insecure --header "$type_header" --header "$auth_header" --request
  POST "$uri" --data "$data"
  ```

- Attach the entire token to your Code Manager URL using the `token` query parameter. For example:

  https://$(puppet config print server):8170/code-manager/v1/webhook?token=<TOKEN>

If you are using a `curl` command to hit the `/webhook` endpoint directly, you must attach the entire token.

**Checking deployment status with a `curl` command**

You can check the status of a deployment by hitting the `status` endpoint.

To use a `curl` command in your custom script, compose a `curl` command to hit the `status` endpoint. You must incorporate a custom URL for Code Manager in the script.

**Troubleshooting Code Manager**

Code Manager requires coordination between multiple components, including r10k and the file sync service. If you have issues with Code Manager, check that these components are functioning.

**Code Manager logs**

Code Manager logs to the Puppet Server log. By default, this log is in `/var/log/puppetlabs/puppetserver/puppetserver.log`. For more information about working with the logs, see the Puppet Server logs documentation.

**Check Code Manager status**

Check the status of Code Manager and file sync if your deployments are not working as expected, or if you need to verify that Code Manager is enabled before running a dependent command.

The command `puppet-code status` verifies that Code Manager and file sync are responding. The command returns the same information as the Code Manager status endpoint. By default, the command returns details at the `info` level; `critical` and `debug` aren’t supported.

The following table shows errors that might appear in the `puppet-code status` output.

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code Manager couldn’t connect to the server</td>
<td>pe-puppetserver process isn’t running</td>
</tr>
<tr>
<td>Code Manager reports invalid configuration</td>
<td>Invalid configuration at <code>/etc/puppetlabs/puppetserver/conf.d/code-manager.conf</code></td>
</tr>
</tbody>
</table>
### Error

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>File sync storage service reports unknown status</td>
<td>Status callback timed out</td>
</tr>
</tbody>
</table>

**Test the connection to the control repository**

The control repository controls the creation of environments, and ensures that the correct versions of all the necessary modules are installed. The master server must be able to access and clone the control repo as the `pe-puppet` user.

To make sure that Code Manager can connect to the control repo, run:

```
puppet-code deploy --dry-run
```

If the connection is set up correctly, this command returns a list of all environments in the control repo or repos. If the command completes successfully, the SSH key has the correct permissions, the Git URL for the repository is correct, and the `pe-puppet` user can perform the operations involved.

If the connection is not working as expected, Code Manager reports an **Unable to determine current branches for Git source** error.

The unsuccessful command also returns a path on the master that you can use for debugging the SSH key and Git URL.

**Check the Puppetfile for errors**

Check the Puppetfile for syntax errors and verify that every module in the Puppetfile can be installed from the listed source. To do this, you need a copy of the Puppetfile in a temporary directory.

Create a temporary directory `/var/tmp/test-puppetfile` on the master for testing purposes, and place a copy of the Puppetfile into the temporary directory.

You can then check the syntax and listed sources in your Puppetfile.

**Check Puppetfile syntax**

To check the Puppetfile syntax, run `r10k puppetfile check` from within the temporary directory.

If you have Puppetfile syntax errors, correct the syntax and test again. When the syntax is correct, the command prints "Syntax OK".

**Check the sources listed in the Puppetfile**

To test the configuration of all sources listed in your Puppetfile, perform a test installation. This test installs the modules listed in your Puppetfile into a modules directory in the temporary directory.

In the temporary directory, run the following command:

```
sudo -H -u pe-puppet bash -c \
   '/opt/puppetlabs/puppet/bin/r10k puppetfile install'
```

This installs all modules listed in your Puppetfile, verifying that you can access all listed sources. Take note of all errors that occur. Issues with individual modules can cause issues for the entire environment. Errors with individual modules (such as Git URL syntax or version issues) show up as general errors for that module.

If you have modules from private Git repositories requiring an SSH key to clone the module, check that you are using the SSH Git URL and not the HTTPS Git URL.

After you've fixed errors, test again and fix any further errors, until all errors are fixed.
Run a deployment test

Manually run a full r10k deployment to check not only the Puppetfile syntax and listed host access, but also whether the deployment works through r10k.

This command attempts a full r10k deployment based on the r10k.yaml file that Code Manager uses. This test writes to the code staging directory only. This does not trigger a file sync and is to be used only for ad-hoc testing.

Run this deployment test with the following command:

```
sudo -H -u pe-puppet bash -c \
'/opt/puppetlabs/puppet/bin/r10k deploy environment -c /opt/puppetlabs/server/data/code-manager/r10k.yaml -p -v debug'
```

If this command completes successfully, the /etc/puppetlabs/code-staging directory is populated with directory-based environments and all of the necessary modules for every environment.

If the command fails, the error is likely in the Code Manager settings specific to r10k. The error messages indicate which settings are failing.

Monitor logs for webhook deployment trigger issues

Issues that occur when a Code Manager deployment is triggered by the webhook can be tricky to isolate. Monitor the logs for the deployment trigger to find the issue.

Deployments triggered by a webhook in Stash/Bitbucket, GitLab, or GitHub are governed by authentication and hit each service's /v1/webhook endpoint.

If you are using a GitLab version older than 8.5.0, Code Manager webhook authentication does not work because of the length of the authentication token. To use the webhook with GitLab, either disable authentication or update GitLab.

**Note:** If you disable webhook authentication, it is disabled only for the /v1/webhook endpoint. Other endpoints (such as /v1/deploys) are still controlled by authentication. There is no way to disable authentication on any other Code Manager endpoint.

To troubleshoot webhook issues, follow the Code Manager webhook instructions while monitoring the Puppet Server log for successes and errors. To do this, open a terminal window and run:

```
tail -f /var/log/puppetlabs/puppetserver/puppetserver.log
```

Watch the log closely for errors and information messages when you trigger the deployment. The puppetserver.log file is the only location these errors appear.

If you cannot determine the problem with your webhook in this step, manually deploy to the /v1/deploys endpoint, as described in the next section.

Monitor logs for /v1/deploys deployment trigger issues

Issues that occur when a Code Manager deployment is triggered by the /v1/deploys endpoint can be tricky to isolate. Monitor the logs for the deployment trigger to find the issue.

Before you trigger a deployment to the /v1/deploys endpoint, generate an authentication token. Then deploy one or more environments with the following command:

**Bash**

```
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8170/code-manager/v1/deploys"
data='{"environments": ["production"], "wait": true}"
```
Managing and deploying Puppet code

```
curl --insecure --header "$type_header" --header "$auth_header" --request
    POST "$uri" --data "$data"
```

This request waits for the deployment and sync to compilers to complete ("wait": true) and so returns errors from the deployment.

Alternatively, you can deploy all environments with the following curl command:

**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8170/code-manager/v1/deploys"
data='{"deploy-all": true, "wait": true}'
curl --insecure --header "$type_header" --header "$auth_header" --request
    POST "$uri" --data "$data"
```

Monitor the `console-services.log` file for any errors that arise from this curl command.

```
tail -f /var/log/puppetlabs/console-services/console-services.log
```

**Code deployments time out**

If your environments are heavily loaded, code deployments can take a long time, and the system can time out before deployment is complete.

If your deployments are timing out too soon, increase your `timeouts_deploy` key. You might also need to increase `timeouts_shutdown`, `timeouts_sync`, and `timeouts_wait`.

**File sync stops when Code Manager tries to deploy code**

Code Manager code deployment involves accessing many small files. If you store your Puppet code on network-attached storage, slow network or backend hardware can result in poor deployment performance.

Tune the network for many small files, or store Puppet code on local or direct-attached storage.

**Classes are missing after deployment**

After a successful code deployment, a class you added isn't showing in the console.

If your code deployment works, but a class you added isn't in the console:

1. Check on disk to verify that the environment folder exists.
2. Check your node group in the **Edit node group metadata** box to make sure it's using the correct environment.
3. Refresh classes.
4. Refresh your browser.

**Code Manager API**

Use Code Manager endpoints to deploy code and query environment deployment status on your masters without direct shell access.

**Authentication**

All Code Manager endpoint requests require token-based authentication. For `/deploys` endpoints, you can pass this token as either an HTTP header or as a query parameter. For the `/webhook` endpoint, you must attach the entire token with the `token` query parameter.

To generate an authentication token, from the command line, run `puppet-access login`. This command stores the token in `~/puppetlabs/token`. To learn more about authentication for Code Manager use, see the related topic about requesting an authentication token.

© 2020 Puppet, Inc.
Pass this token as either an X-Authentication HTTP header or as the token query parameter with your request. If you pass the token as a query parameter, it might show up in access logs.

For example, an HTTP header for the /deploys endpoint looks something like:

**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8170/code-manager/v1/deploys"
data='{"environments": ["production"], "wait": true}'

curl --insecure --header "$type_header" --header "$auth_header" --request POST "$uri" --data "$data"
```

```bash
$pe_headers = @{
    "X-Authentication" = "AMI1Wlel2Ybd2Lqu-hdhHaLWCkfvgSgl83UgKdwzixwe";
}
$pe_codemgr_hash = [ordered]@{
    environments = @("production")
}

# Generate JSON object from pe_codemgr_hash
$JSON = $pe_codemgr_hash | convertto-json -compress
Invoke-RestMethod -SkipCertificateCheck -ContentType "application/json" -uri $pe_uri -Method POST -Body $JSON -Headers $pe_headers
```

Passing the token with the token query parameter might look like:

**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
uri="https://$(puppet config print server):8170/code-manager/v1/webhook?type=github&token=$(puppet-access show)"
data='{"environments": ["production"], "wait": true}'

APIs allow you to interact with Puppet and Puppet Enterprise (PE) applications from your own code or application integration hooks.

POST /v1/deploys
Use the Code Manager/deploys endpoint to queue code deployments.

Request format
The body of the POST /deploys request must be a JSON object that includes the authentication token and a URL containing:

- The name of the master server, such as master.example.com
- The Code Manager port, such as 8170.
- The endpoint.

The request must also include either:

- The "environments" key, with or without the "wait" key.
- The "deploy-all" key, with or without the "wait" key.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;environments&quot;</td>
<td>Specifies the environments for which to queue code deployments. If not specified, the &quot;deploy-all&quot; key must be specified.</td>
<td>Accepts a comma- and space-separated list of strings specifying environments.</td>
</tr>
<tr>
<td>&quot;deploy-all&quot;</td>
<td>Specifies whether Code Manager deploys all environments or not. If specified true, Code Manager determines the most recent list of environments and queues a deploy for each one. If specified false or not specified, the &quot;environments&quot; key must be specified with a list of environments.</td>
<td>true, false</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>&quot;deploy-modules&quot;</td>
<td>Specifies whether Code Manager deploys modules from the Puppetfile.</td>
<td>true, false</td>
</tr>
<tr>
<td></td>
<td>If specified true or not specified, Code Manager deploys modules. If specified false, modules aren’t deployed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>**Note: **To ensure environments are populated before use, modules are deployed on the first deployment of an environment, even if you pass &quot;deploy-modules&quot;: false.</td>
<td></td>
</tr>
<tr>
<td>&quot;modules&quot;</td>
<td>Specifies the modules to be deployed to the selected environments.</td>
<td>Accepts a comma- and space-separated list of modules to deploy.</td>
</tr>
<tr>
<td>&quot;wait&quot;</td>
<td>Specifies whether Code Manager must wait for all deploys to finish or error before it returns a response.</td>
<td>true, false</td>
</tr>
<tr>
<td></td>
<td>If specified true, Code Manager returns a response after all deploys have either finished or errored. If specified false or not specified, returns a response showing that deploys are queued.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Specify together with the &quot;deploy-all&quot; or &quot;environment&quot; keys.</td>
<td></td>
</tr>
<tr>
<td>&quot;dry-run&quot;</td>
<td>Tests the Code Manager connection to each of the configured remotes and attempts to fetch a list of environments from each, reporting any connection errors.</td>
<td>true, false</td>
</tr>
<tr>
<td></td>
<td>Specify together with the &quot;deploy-all&quot; or &quot;environment&quot; keys.</td>
<td></td>
</tr>
</tbody>
</table>

For example, to deploy the production and testing environments and return results after the deployments complete or fail, pass the "environments" key with the "wait" key:

**Bash**

```
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
cacert="$(puppet config print localcacert)"
uri="https://$(puppet config print server):8170/code-manager/v1/deploys"
data='{"environments": ["production", "testing"], "wait": true}'
curl --header "$type_header" --header "$auth_header" --cacert "$cacert" --request POST "$uri" --data "$data"
```

To deploy all configured environments and return only the queuing results, pass the "deploy-all" key without the "wait" key:
**Bash**

```bash
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
cacert="$(puppet config print localcacert)"
uri="https://$(puppet config print server):8170/code-manager/v1/deploys"
data='{"deploy-all": true}"

curl --header "$type_header" --header "$auth_header" --cacert "$cacert" --request POST "$uri" --data "$data"
```

**Response format**

The POST /deploys response contains a list of objects, each containing data about a queued or deployed environment.

If the request did not include a "wait" key, the response returns each environment's name and status.

If the "wait" key was included in the request, the response returns information about each deployment. This information includes a deploy-signature, which is the commit SHA of the control repo that Code Manager used to deploy the environment. The output also includes two other SHAs that indicate that file sync is aware that the environment has been deployed to the code staging directory.

The response shows any deployment failures, even after they have successfully deployed. The failures remain in the response until cleaned up by garbage collection.

**Key** | **Description** | **Value**
--- | --- | ---
"environment" | The name of the environment queued or deployed. | A string specifying the name of an environment.
"id" | Identifies the queue order of the code deploy request. | An integer generated by Code Manager.
"status" | The status of the code deployment for that environment. | Can be one of the following:
• "new": The deploy request has been accepted but not yet queued.
• "complete": The deploy is complete and has been synced to the live code directory on masters.
• "failed": The deploy failed.
• "queued": The deploy is queued and waiting.
"deploy-signature" | The commit SHA of the control repo that Code Manager used to deploy code in that environment. | A Git SHA.
"file-sync" | Commit SHAs used internally by file sync to identify the code synced to the code staging directory | Git SHAs for the "environment-commit" and "code-commit" keys.

For example, for a /deploys request without the "wait" key, the response shows only "new" or "queued" status, because this response is returned as soon as Code Manager accepts the request.

```json
[
  {
    "environment": "production",
    "id": 1,
```
If you pass the "wait" key with your request, Code Manager doesn't return any response until the environment deployments have either failed or completed. For example:

```json
[
  {
    "deploy-signature": "482f8d3adc76b5197306c5d4c8aa32aa8315694b",
    "file-sync": {
      "environment-commit": "6939889b679fde1449545c44f26aa06174d25c21",
      "code-commit": "ce5f7158615759151f77391c7b2b8b497aaebce1"
    },
    "environment": "production",
    "id": 3,
    "status": "complete"
  }
]
```

### Error responses

If any deployments fail, the response includes an error object for each failed environment. Code Manager returns deployment results only if you passed the "wait" key; otherwise, it returns queue information.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;environment&quot;</td>
<td>The name of the environment queued or deployed.</td>
<td>A string specifying the name of an environment.</td>
</tr>
<tr>
<td>&quot;error&quot;</td>
<td>Information about the deployment failure.</td>
<td>Contains keys with error details.</td>
</tr>
<tr>
<td>&quot;corrected-env-name&quot;</td>
<td>The name of the environment.</td>
<td>A string specifying the name.</td>
</tr>
<tr>
<td>&quot;kind&quot;</td>
<td>The kind of error encountered.</td>
<td>An error type.</td>
</tr>
<tr>
<td>&quot;msg&quot;</td>
<td>The error message.</td>
<td>An error message.</td>
</tr>
<tr>
<td>&quot;id&quot;</td>
<td>Identifies the queue order of the code deploy request.</td>
<td>An integer generated by Code Manager.</td>
</tr>
<tr>
<td>&quot;status&quot;</td>
<td>The status of the requested code deployment.</td>
<td>For errors, status is &quot;failed&quot;.</td>
</tr>
</tbody>
</table>

For example, information for a failed deploy of an environment might look like:

```json
{
  "environment": "test14",
  "error": {
    "details": {
      "corrected-env-name": "test14"
    },
    "kind": "puppetlabs.code-manager/deploy-failure",
    "msg": "Errors while deploying environment 'test14' (exit code: 1):
    Authentication failed for Git remote "https://github.com/puppetlabs/puffpetlabs-apache"."
  },
  "id": 52,
}
```

"status": "failed"
}

POST /v1/webhook
Use the Code Manager /webhook endpoint to trigger code deploys based on your control repo updates.

Request format
The POST /webhook request consists of a specially formatted URL that specifies the webhook type, an optional branch prefix, and a PE authentication token.

You must pass the authentication token with the token query parameter. To use a GitHub webhook with the Puppet signed certificate, you must disable SSL verification.

In your URL, include:

- The name of the Puppet master server (for example, master.example.com)
- The Code Manager port (for example, 8170)
- The endpoint (/v1/webhook)
- The type parameter with a valid value, such as gitlab.
- The prefix parameter and value.
- The token parameter with the complete token.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Required. Specifies what type of POST body to expect.</td>
<td>github, gitlab, tfs-git, bitbucket, stash</td>
</tr>
<tr>
<td>prefix</td>
<td>Optional. Specifies a prefix to use in translating branch names to environments.</td>
<td>A string specifying a branch prefix.</td>
</tr>
<tr>
<td>token</td>
<td>Specifies the PE authorization token to use. Required unless you disable webhook_authentication in Code Manager configuration.</td>
<td>The complete authentication token.</td>
</tr>
</tbody>
</table>

For example, a GitHub webhook might look like this:

```
https://master.example.com:8170/code-manager/v1/webhook?type=github&token= $TOKEN
```

A Stash webhook with the optional prefix parameter specified might look like:

```
https://master.example.com/code-manager/v1/webhook?
type=stash&prefix=dev&token=$TOKEN
```

You must attach the complete authentication token to the request. A GitHub request with the entire token attached might look like this:

```
https://master.example.com:8170/code-manager/v1/webhook?
type=github&token=eyJhbGciOiJSUzUxMiIsInR5cCI6IkpXVCJ9.eyJpc3MiOiJkZXBsb3kiLCJpYXQiOjE0NDY2NjQ1OTAsImV4cCI6MTQ3ODI4Njk5MCwic3ViIjp7ImlkIjoiZWNmOTJlYzYtMjg1Zi00NzExLWI0MDktMzFmMGYzMGIzOGUwIiwibG9naW4iOiJkZXBsb3kifX0.OdEIA-HGRC0r2J87Pj2sDsyz-EMK-7sZalBTswy2e3uSv1Z6ulXaIQq69PQnSSEwExQotExDqXZInyQa_le2gwTo4smjUaBd6_LnPYr6GJ4hjB4-fT8dNnVuvZaE5WPkKt-sNJkJwE9LiEd4W42aCYfse1KNgPuXR5m77SRsUy86ymVxPKHqqexEyvS7LGeQJvyQE1qEejSdbILg6zn1JXhg1K
```

© 2020 Puppet, Inc.
Response format

When you trigger your webhook by pushing changes to your control repository, you can see the response in your Git provider interface. Code Manager does not give a command line response to typical webhook usage.

If you hit the webhook endpoint directly using a curl command with a properly formatted request, valid authentication token, and a valid value for the "type" parameter, Code Manager returns a {"status":"OK"} response, whether or not code successfully deployed.

Error responses

When you trigger your webhook by pushing changes to your control repository, you can see any errors in your Git provider interface. Code Manager does not give a command line response to typical webhook usage.

If you hit the webhook endpoint directly using a curl command with a request that has an incorrect "type" value or no "type" value, you get an error response such as:

```
{"kind":"puppetlabs.code-manager/unrecognized-webhook-type","msg":"Unrecognized webhook type: 'githubby'","details":"Currently supported valid webhook types include: github gitlab stash tfs-git bitbucket"}
```

**GET /v1/deploys/status**

Use the Code Manager /deploys/status endpoint to return the status of the code deployments that Code Manager is processing for each environment.

**Request format**

The body of the GET /deploys/status request must include the authentication token and a URL containing:

- The name of the master server, such as master.example.com.
- The Code Manager port, such as 8170.
- The endpoint.

**Bash**

```
type_header='Content-Type: application/json'
auth_header="X-Authentication: $(puppet-access show)"
url="https://$(puppet config print server):8170/code-manager/v1/deploys/status"
curl --insecure --header "$type_header" --header "$auth_header" --header "$type_header" "$url"
```

**Response format**

The /deploys/status endpoint responds with a list of the code deployment requests that Code Manager is processing.

The response contains three sections:
• "deploy-status": Lists the status for each code deployment that Code Manager is processing, including failed deployments. Deployments can be "queued", "deploying", "new", or "failed". Environments that have been successfully deployed to either the code staging or live code directories are displayed in the "file-sync-storage-status" or "file-sync-client-status" sections, respectively.

• "file-sync-storage-status": Lists all environments that Code Manager has successfully deployed to the code staging directory, but not yet synced to the live code directory.

• "file-sync-client-status": Lists status for each master that Code Manager is deploying environments to, including whether the code in the master's staging directory has been synced to its live code directory.

The response can contain the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;queued&quot;</td>
<td>The environment is queued for deployment.</td>
<td>For each environment:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;environment&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;queued-at&quot;</td>
</tr>
<tr>
<td>&quot;deploying&quot;</td>
<td>The environment is in the process of being deployed.</td>
<td>For each environment:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;environment&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;queued-at&quot;</td>
</tr>
<tr>
<td>&quot;new&quot;</td>
<td>Code Manager has accepted a request to deploy the environment, but has not yet queued it.</td>
<td>For each environment:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;environment&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;queued-at&quot;</td>
</tr>
<tr>
<td>&quot;failed&quot;</td>
<td>The code deployment for the environment has failed.</td>
<td>For each environment:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;environment&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;error&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;details&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;corrected-env-name&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;kind&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;msg&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;queued-at&quot;</td>
</tr>
<tr>
<td>&quot;environment&quot;</td>
<td>The name of the environment.</td>
<td>A string that is the name of the environment.</td>
</tr>
<tr>
<td>&quot;queued-at&quot;</td>
<td>The date and time when the environment was queued.</td>
<td>A date and time stamp.</td>
</tr>
<tr>
<td>&quot;deployed&quot;</td>
<td>Lists information for each deployed environment.</td>
<td>For each environment:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;environment&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;queued-at&quot;</td>
</tr>
<tr>
<td>&quot;date&quot;</td>
<td>The date and time the operation was completed.</td>
<td>A date and time stamp.</td>
</tr>
<tr>
<td>&quot;deploy-signature&quot;</td>
<td>The commit SHA of the control repo used to deploy the environment.</td>
<td>A Git SHA.</td>
</tr>
<tr>
<td>&quot;all-synced&quot;</td>
<td>Whether all requested code deployments have been synced to the live code directories on their respective masters.</td>
<td>true, false</td>
</tr>
<tr>
<td>Key</td>
<td>Definition</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>&quot;file-sync-clients&quot;</td>
<td>List of all masters that Code Manager is deploying code to.</td>
<td>For each environment listed:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;last_check_in_time&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;synced-with-file-sync-storage&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;deployed&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;environment&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;date&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;deploy-signature&quot;</td>
</tr>
<tr>
<td>&quot;last_check_in_time&quot;</td>
<td>The most recent time that the live code directory checked in for new code</td>
<td>A date and time stamp.</td>
</tr>
<tr>
<td></td>
<td>from the staging directory.</td>
<td></td>
</tr>
<tr>
<td>&quot;synced-with-file-sync-storage&quot;</td>
<td>Whether the live code directory has been synced with the code staging</td>
<td>true,false</td>
</tr>
<tr>
<td></td>
<td>directory on a given master.</td>
<td></td>
</tr>
</tbody>
</table>

For example, a complete response to a request might look like:

```json
{
    "deploys-status":{
        "queued":[
            {
                "environment":"dev",
                "queued-at":"2018-05-15T17:42:34.988Z"
            }
        ],
        "deploying":[
            {
                "environment":"test",
                "queued-at":"2018-05-15T17:42:34.988Z"
            },
            {
                "environment":"prod",
                "queued-at":"2018-05-15T17:42:34.988Z"
            }
        ],
        "new":[
        ],
        "failed":[
        ]
    },
    "file-sync-storage-status":{
        "deployed":[
            {
                "environment":"prod",
                "date":"2018-05-10T21:44:24.000Z",
                "deploy-signature":"66d620604c9465b464a3dac4884f96c43748b2c5"
            },
            {
                "environment":"test",
                "date":"2018-05-10T21:44:25.000Z",
                "deploy-signature":"24ecc7bac8a4d7276a3a2350b6fda53812ee86f"
            },
            {
                "environment":"dev",
```
"date": "2018-05-10T21:44:21.000Z",
"deploy-signature": "503a335c99a190501456194d13ff722194e55613"
}
],
"file-sync-client-status": {
  "all-synced": false,
  "file-sync-clients": {
    "chihuahua": {
      "last_check_in_time": null,
      "synced-with-file-sync-storage": false,
      "deployed": []
    },
    "localhost": {
      "synced-with-file-sync-storage": true,
      "deployed": [
        {
          "environment": "prod",
          "date": "2018-05-11T22:40:48.000Z",
          "deploy-signature": "66d620604c9465b464a3dac4884f96c43748b2c5"
        },
        {
          "environment": "test",
          "date": "2018-05-11T22:40:48.000Z",
          "deploy-signature": "24ec7bac8a4d727d6a3a2350b6fda53812ee86f"
        },
        {
          "environment": "dev",
          "date": "2018-05-11T22:40:50.000Z",
          "deploy-signature": "503a335c99a190501456194d13ff722194e55613"
        }
      ]
    }
  }
}

Error responses

If code deployment fails, the "deploys-status" section of the response provides an "error" key for the environment with the failure. The "error" key contains information about the failure.

Deployment failures can remain in the response even after the environment in question is successfully deployed. Old failures are removed from the "deploys-status" response during garbage collection.

<table>
<thead>
<tr>
<th>Key</th>
<th>Definition</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;environment&quot;</td>
<td>The name of the environment queued or deployed.</td>
<td>A string specifying the name of an environment.</td>
</tr>
<tr>
<td>&quot;error&quot;</td>
<td>Information about the deployment failure.</td>
<td>Contains keys with error details.</td>
</tr>
<tr>
<td>&quot;corrected-env-name&quot;</td>
<td>The name of the environment.</td>
<td>A string specifying the name.</td>
</tr>
<tr>
<td>&quot;kind&quot;</td>
<td>The kind of error encountered.</td>
<td>An error type.</td>
</tr>
<tr>
<td>&quot;msg&quot;</td>
<td>The error message.</td>
<td>An error message.</td>
</tr>
</tbody>
</table>
For example, with a failure, the "deploys-status" response section might look something like:

```
[
  {
    "deploys-status": {
      "deploying": [],
      "failed": [
        {
          "environment": "test14",
          "error": {
            "details": {
              "corrected-env-name": "test14"
            },
            "kind": "puppetlabs.code-manager/deploy-failure",
            "msg": "Errors while deploying environment 'test14' (exit code: 1):
ERROR	 -> Authentication failed for Git remote "https://github.com/puppetlabs/puffppetlabs-apache",
          }
        },
      ]
    }]
```

Managing code with r10k

r10k is a code management tool that allows you to manage your environment configurations (such as production, testing, and development) in a source control repository.

Based on the code in your control repo branches, r10k creates environments on your master and installs and updates the modules you want in each environment. If you are running PE 2015.3 or later, we encourage you to use Code Manager, which uses r10k in the background to automate the deployment of your code. If you use Code Manager, you won't need to manage or interact with r10k manually. To learn more about Code Manager and begin setup, see the Code Manager page. However, if you're already using r10k and aren't ready to switch to Code Manager, you can continue using r10k alone.

To set up r10k to manage your environments:

1. Set up a control repository for your code.
2. Create a Puppetfile to manage the content for your environment.
3. Configure r10k. Optionally, you can also customize your r10k configuration in Hiera.
4. Run r10k to deploy your environments and modules.

We've also included a reference of r10k subcommands.
When performing a fresh text-mode installation of Puppet Enterprise (PE), you can configure r10k by adding parameters to the `pe.conf` file. In existing installations, configure r10k by adjusting parameters in the console.

**CAUTION:** Do not edit the r10k configuration file manually. Puppet manages this configuration file automatically and undoes any manual changes you make.

**Related information**

Configuration parameters and the `pe.conf` file on page 97

A `pe.conf` file is a HOCON formatted file that declares parameters and values used to install, upgrade, or configure PE. A default `pe.conf` file is available in the `conf.d` directory in the installer tarball.

Upgrading from previous versions of r10k

If you used r10k prior to PE version 2015.3, you might have configured it in the console using the `pe_r10k` class. We suggest configuring r10k in the master profile class, and then customizing your configuration as needed in Hiera. This simplifies configuration, and makes it easier to move to Code Manager in the future.

To switch to master profile class configuration, remove the `pe_r10k` class in the console, and then configure r10k as described in the topic about configuring r10k after PE installation. You can then customize your configuration in Hiera if needed.

**Note:** If you were using earlier versions of r10k with the `zack-r10k` module, discontinue use of the module and switch to the master profile configuration as above.

**Configure r10k during installation**

To set up r10k during PE installation, add the r10k parameters to `pe.conf` *before* starting installation. This is the easiest way to set up r10k with a new PE installation.

**Before you begin**

Ensure that you have a Puppetfile and a control repo. You also need the SSH private key that you created when you made your control repo.

**Restriction:** This configuration method works only with text-based installation. If you are using the web-based installer, see the related topic about configuring r10k after PE installation.

1. Add `puppet_enterprise::profile::master::r10k_remote` to `pe.conf`.

   This setting specifies the location of the control repository. It accepts a string that is a valid URL for your Git control repository.

```
"puppet_enterprise::profile::master::r10k_remote":
  "git@<YOUR.GIT.SERVER.COM>:puppet/control.git"
```
2. Add `puppet_enterprise::profile::master::r10k_private_key` to `pe.conf`.

   This setting specifies the path to the file that contains the SSH private key used to access your Git repositories. This location for the SSH private key file, which you created when you set up your control repository, must be located on the Puppet master and owned by and accessible to the `pe-puppet` user. The setting accepts a string `r10k`:

   "puppet_enterprise::profile::master::r10k_private_key": "/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa"

3. Complete PE installation. The installer configures r10k for you. You can change the values for the remote and the private key as needed in the master profile settings in the console.

4. After PE installation is complete, place the SSH private key you created when you set up your control repository in the `r10k_private_key` location.

5. Run r10k. PE does not automatically run r10k.

### Configure r10k after PE installation

To configure r10k in an existing PE, set r10k parameters in the console. You can also adjust r10k settings in the console.

**Before you begin**

Ensure that you have a Puppetfile and a control repo. You also need the SSH private key that you created when you made your control repo.

1. In the console, set the following parameters in the `puppet_enterprise::profile::master` class in the PE Master node group:

   - `r10k_remote`
     
     This is the location of your control repository. Enter a string that is a valid URL for your Git control repository, such as "git@<YOUR.GIT.SERVER.COM>:puppet/control.git".

   - `r10k_private_key`
     
     This is the path to the private key that permits the `pe-puppet` user to access your Git repositories. This file must be located on the Puppet master, owned by the `pe-puppet` user, and in a directory that the `pe-puppet` user has permission to view. We recommend `/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa`. Enter a string, such as "/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa".

2. Run Puppet on all of your masters.

   You can now customize your r10k configuration in Hiera, if needed. After r10k is configured, you can deploy your environments from the command line. PE does not automatically run r10k at the end of installation.

### Customizing r10k configuration

If you need a customized r10k configuration, you can set specific parameters with Hiera.

To customize your configuration, add keys to your control repository hierarchy in the `data/common.yaml` file in the format `pe_r10k::<parameter>`.

In this example, the first parameter specifies where to store the cache of your Git repos, and the second sets where the source repository should be fetched from.

   `pe_r10k::cachedir: /var/cache/r10k`
   `pe_r10k::remote: git://git-server.site/my-org/main-modules`

**Remember:** After changing any of these settings, run r10k on the command line to deploy your environments. PE does not automatically run r10k at the end of installation.

**Related information**

Configure settings with Hiera on page 152
Hiera is a hierarchy-based method of configuration management that relies on a “defaults, with overrides” system. When you add a parameter or setting to your Hiera data, Hiera searches through the data in the order it was written to find the value you want to change. Once found, it overrides the default value with the new parameter or setting. You can use Hiera to manage your PE configuration settings.

**Add r10k parameters in Hiera**
To customize your r10k configuration, add parameters to your control repository hierarchy in the data/common.yaml file.

1. Add the parameter in the data/common.yaml file in the format `pe_r10k::<parameter>`.
2. Run Puppet on the master to apply changes.

**Configuring Forge settings**
To configure how r10k downloads modules from the Forge, specify `forge_settings` in Hiera.

This parameter configures where Forge modules should be installed from, and sets a proxy for all Forge interactions. The `forge_settings` parameter accepts a hash with the following values:

- **baseurl**
- **proxy**

**baseurl**
Indicates where Forge modules should be installed from. Defaults to `https://forgeapi.puppetlabs.com`.

```
pe_r10k::forge_settings:
  baseurl: 'https://private-forge.mysite'
```

**proxy**
Sets the proxy for all Forge interactions.

This setting overrides the global `proxy` setting on Forge operations only. You can set an unauthenticated proxy or an authenticated proxy with either Basic or Digest authentication. See the global `proxy` setting for more information and examples.

```
proxy: 'http://proxy.example.com:3128'
```

**Configuring purge levels**
The `purge_levels` setting controls which unmanaged content r10k purges during a deployment.

This setting accepts an array of strings specifying what content r10k purges during code deployments. Available values are:

- **deployment**
- **environment**
- **puppetfile**
- **purge_whitelist**

The default value for this setting is `['deployment', 'puppetfile']`. With these values, r10k purges:

- Any content that is not managed by the sources declared in the remote or sources settings.
- Any content that is not declared in the Puppetfile, but is found in a directory managed by the Puppetfile.

```
deploy:
  purge_levels: ['deployment', 'environment', 'puppetfile']
```
deployment

After each deployment, in the configured basedir, r10k recursively removes content that is not managed by any of the sources declared in the `remote` or `sources` parameters.

Disabling this level of purging could cause the number of deployed environments to grow without bound, because deleting branches from a control repo would no longer cause the matching environment to be purged.

environment

After a given environment is deployed, r10k recursively removes content that is neither committed to the control repo branch that maps to that environment, nor declared in a Puppetfile committed to that branch.

With this purge level, r10k loads and parses the Puppetfile for the environment even if the `--puppetfile` flag is not set. This allows r10k to check whether or not content is declared in the Puppetfile. However, Puppetfile content is deployed only if the environment is new or the `--puppetfile` flag is set.

If r10k encounters an error while evaluating the Puppetfile or deploying its contents, no environment-level content is purged.

puppetfile

After Puppetfile content for a given environment is deployed, r10k recursively removes content in any directory managed by the Puppetfile, if that content is not also declared in that Puppetfile.

Directories considered to be managed by a Puppetfile include the configured `moduledir` (which defaults to "modules"), as well as any alternate directories specified as an `install_path` option to any Puppetfile content declarations.

purge_whitelist

The `purge_whitelist` setting exempts the specified filename patterns from being purged.

This setting affects environment level purging only. Any given value must be a list of shell style filename patterns in string format.

See the Ruby documentation for the `fnmatch` method for more details on valid patterns. Both the `FNM_PATHNAME` and `FNM_DOTMATCH` flags are in effect when r10k considers the whitelist.

Patterns are relative to the root of the environment being purged and, by default, do not match recursively. For example, a whitelist value of `*myfile*` would preserve only a matching file at the root of the environment. To preserve the file throughout the deployed environment, you would need to use a recursive pattern such as `/**/ *myfile*`.

Files matching a whitelist pattern might still be removed if they exist in a folder that is otherwise subject to purging. In this case, use an additional whitelist rule to preserve the containing folder.

```yaml
deploy:
  purge_whitelist: [ 'custom.json', '**/*.xpp' ]
```

Locking r10k deployments

The `deploy: write_lock` setting allows you to temporarily disallow r10k code deploys without completely removing the r10k configuration.

This deploy subsetting is useful to prevent r10k deployments at certain times or to prevent deployments from interfering with a common set of code that might be touched by multiple r10k configurations.

```yaml
deploy:
  write_lock: "Deploying code is disallowed until the next maintenance window."
```
## Configuring sources

If you are managing more than one repository with r10k, specify a map of your source repositories.

Use the `source` parameter to specify a map of sources. Configure this setting if you are managing more than just Puppet environments, such as when you are also managing Hiera data in its own control repository.

To use multiple control repos, the `sources` setting and the `repositories` setting must match.

If `sources` is set, you cannot use the global `remote` and `r10k_basedir` settings. Note that r10k raises an error if different sources collide in a single base directory. If you are using multiple sources, use the `prefix` option to prevent collisions.

This setting accepts a hash with the following subsettings:

- `remote`
- `basedir`
- `prefix`
- `invalid_branches`

```plaintext
myorg:
    remote: "git://git-server.site/myorg/main-modules"
    basedir: "/etc/puppetlabs/puppet/environments"
    prefix: true
    invalid_branches: 'error'

mysource:
    remote: "git://git-server.site/mysource/main-modules"
    basedir: "/etc/puppetlabs/puppet/environments"
    prefix: "testing"
    invalid_branches: 'correct_and_warn'
```

### remote

Specifies where the source repository should be fetched from. The remote must be able to be fetched without any interactive input. That is, you cannot be prompted for usernames or passwords in order to fetch the remote.

Accepts a string that is any valid URL that r10k can clone, such as:

```plaintext
git://git-server.site/my-org/main-modules
```

### basedir

Specifies the path where environments are created for this source. This directory is entirely managed by r10k, and any contents that r10k did not put there are removed.

Note that the `basedir` setting must match the `environmentpath` in your puppet.conf file, or Puppet won't be able to access your new directory environments.

### prefix

Allows environment names to be prefixed with this string. Alternatively, if `prefix` is set to true, the source's name is used. This prevents collisions when multiple sources are deployed into the same directory.

In the `sources` example above, two "main-modules" environments are set up in the same base directory. The prefix setting is used to differentiate the environments: the first is named "myorg-main-modules", and the second is "testing-main-modules".

### ignore_branch_prefixes

Causes branches from a source which match any of the prefixes listed in the setting to be ignored. The match can be full or partial. On deploy, each branch in the repo has its name tested against all prefixes listed in `ignore_branch_prefixes` and, if the prefix is found, then an environment is not deployed for this branch.
The setting is a list of strings. In the following example, branches in "mysource" with the prefixes "test" and "dev" are not deployed.

```yaml
---
sources:
  mysource:
    basedir: '/etc/puppet/environments'
    ignore_branch_prefixes:
      - 'test'
      - 'dev'
```

If `ignore_branch_prefixes` is not specified, then all branches are deployed.

**invalid_branches**

Specifies how branch names that cannot be cleanly mapped to Puppet environments are handled. This option accepts three values:

- 'correct_and_warn' is the default value and replaces non-word characters with underscores and issues a warning.
- 'correct' replaces non-word characters with underscores without warning.
- 'error' ignores branches with non-word characters and issues an error.

**Configuring the r10k base directory**

The r10k base directory specifies the path where environments are created for this source.

This directory is entirely managed by r10k, and any contents that r10k did not put there are removed. If `r10k_basedir` is not set, it uses the default `environmentpath` in your `puppet.conf` file. If `r10k_basedir` is set, you cannot set the `sources` parameter.

Note that the `r10k_basedir` setting **must match** the `environmentpath` in your `puppet.conf` file, or Puppet won’t be able to access your new directory environments.

Accepts a string, such as: `/etc/puppetlabs/code/environments`.

**Configuring r10k Git settings**

To configure r10k to use a specific Git provider, a private key, a proxy, or multiple repositories with Git, specify the `git_settings` parameter.

The r10k `git_settings` parameter accepts a hash of the following settings:

- `private_key`
- `proxy`
- `repositories`
- `provider`

Contains settings specific to Git. Accepts a hash of values, such as:

```yaml
pe_r10k::git_settings:
  provider: "rugged"
  private_key: "/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa"
  username: "git"
```

**private_key**

Specifies the file containing the default private key used to access control repositories, such as `/etc/puppetlabs/puppetserver/ssh/id-control_repo.rsa`. This file must have read permissions for the pe-puppet user. The SSH key cannot require a password. This setting is required, but by default, the value is supplied by the master profile in the console.
proxy
Sets a proxy specifically for Git operations that use an HTTP(S) transport.

This setting overrides the global proxy setting on Git operations only. You can set an unauthenticated proxy or an authenticated proxy with either Basic or Digest authentication. To set a proxy for a specific Git repository only, set proxy in the repositories subsetting of git_settings. See the global proxy setting for more information and examples.

proxy: 'http://proxy.example.com:3128'

repositories
Specifies a list of repositories and their respective private keys. Use this setting if you want to use multiple control repos.

To use multiple control repos, the sources setting and the repositories setting must match. Accepts an array of hashes with the following keys:

• remote: The repository these settings should apply to.
• private_key: The file containing the private key to use for this repository. This file must have read permissions for the pe-puppet user. This setting overrides the global private_key setting.
• proxy: The proxy setting allows you to set or override the global proxy setting for a single, specific repository. See the global proxy setting for more information and examples.

pe_r10k::git_settings:
  repositories:
    - remote: "ssh://tessier-ashpool.freeside/protected-repo.git"
      private_key: "/etc/puppetlabs/r10k/ssh/id_rsa-protected-repo-deploy-key"
    - remote: "https://git.example.com/my-repo.git"
      proxy: "https://proxy.example.com:3128"

username
Optionally, specify a username when the Git remote URL does not provide a username.

Configuring proxies
To configure proxy servers, use the proxy setting. You can set a global proxy for all HTTP(S) operations, for all Git or Forge operations, or for a specific Git repository only.

proxy
To set a proxy for all operations occurring over an HTTP(S) transport, set the global proxy setting. You can also set an authenticated proxy with either Basic or Digest authentication.

To override this setting for Git or Forge operations only, set the proxy subsetting under the git_settings or forge_settings parameters. To override for a specific Git repository, set a proxy in the repositories list of git_settings. To override this setting with no proxy for Git, Forge, or a particular repository, set that specific proxy setting to an empty string.

In this example, the first proxy is set up without authentication, and the second proxy uses authentication:

proxy: 'http://proxy.example.com:3128'
proxy: 'http://user:password@proxy.example.com:3128'

r10k proxy defaults and logging
By default, r10k looks for and uses the first environment variable it finds in this list:
• HTTPS_PROXY
• https_proxy
• HTTP_PROXY
• http_proxy

If no proxy setting is found in the environment, the global proxy setting defaults to no proxy.

The proxy server used is logged at the "debug" level when r10k runs.

**Configuring postrun commands**

To configure a command to be run after all deployment is complete, add the postrun parameter.

The postrun optional command to be run after r10k finishes deploying environments. The command must be an array of strings to be used as an argument vector. You can set this parameter only one time.

```bash
postrun: ['/usr/bin/curl', '-F', 'deploy=done', 'http://my-app.site/endpoint']
```

**r10k parameters**

The following parameters are available for r10k. Parameters are optional unless otherwise stated.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Value</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>cachedir</td>
<td>Specifies the path to the directory where you want the cache of your Git repos to be stored.</td>

**Deploying environments with r10k**

Deploy environments on the command line with the r10k command.

The first time you run r10k, deploy all environments and modules by running `r10k deploy environment`.

This command:

1. Checks your control repository to see what branches are present.
2. Maps those branches to the Puppet directory environments.
3. Clones your Git repo, and either creates (if this is your first run) or updates (if it is a subsequent run) your directory environments with the contents of your repo branches.

**Note:**

When running commands to deploy code on a master, r10k needs write access to your environment path. Run r10k as the `pe-puppet` user or as root. Running the user as root requires access control to the root user.

**Updating environments**

To update environments with r10k, use the `deploy environment` command.

**Updating all environments**

The `deploy environment` command updates all existing environments and recursively creates new environments.

The `deploy environment` command updates all existing environments and recursively creates new environments. This command updates modules only on the first deployment of a given environment. On subsequent updates, it updates only the environment itself.

From the command line, run `r10k deploy environment`
Updating all environments and modules
With the --puppetfile flag, the deploy environment command updates all environments and modules.

This command:
• Updates all sources.
• Creates new environments.
• Deletes old environments.
• Recursively updates all environment modules specified in each environment's Puppetfile.

This command does the maximum possible work, and is therefore the slowest method for r10k deployments. Usually, you should use the less resource-intensive commands for updating environments and modules.

From the command line, run r10k deploy environment --puppetfile

Updating a single environment
To updated just one environment, specify that environment name with the deploy environment command.

This command updates modules only on the first deployment of the specified environment. On subsequent updates, it updates only the environment itself.

If you're actively developing on a given environment, this is the quickest way to deploy your changes.

On the command line, run r10k deploy environment <MY_WORKING_ENVIRONMENT>

Updating a single environment and its modules
To update both a single given environment and all of the modules contained in that environment's Puppetfile, add the --puppetfile flag to your command. This is useful if you want to make sure that a given environment is fully up to date.

On the command line, run r10k deploy environment <MY_WORKING_ENVIRONMENT> --puppetfile

Installing and updating modules
To update modules, use the r10k deploy module subcommand. This command installs or updates the modules you've specified in each environment's Puppetfile.

If the specified module is not described in a given environment's Puppetfile, that environment is skipped.

Updating specific modules across all environments
To update specific modules across all environments, specify the modules with the deploy module command.

You can specify a single module or multiple modules. This is useful when you're working on a module and want to update it across all environments.

For example, to update the apache, jenkins, and java modules, run r10k deploy module apache jenkins java

Updating one or more modules in a single environment
To update specific modules in a single environment, specify both the environment and the modules.

On the command line, run r10k deploy module with:
• The environment option -e.
• The name of the environment.
• The names of the modules you want to update in that environment.

For example, to install the apache, jenkins, and java modules in the production environment, run r10k deploy module -e production apache jenkins java

Viewing environments with r10k
Display information about your environments and modules with the r10k deploy display subcommand. This subcommand does not deploy environments, but only displays information about the environments and modules r10k is managing.

This command can return varying levels of detail about the environments.
• To display all environments being managed by r10k, use the `deploy display` command. From the command line, run `r10k deploy display`.

• To display all managed environments and Puppetfile modules, use the `Puppetfile` flag, `-p`. From the command line, run `r10k deploy display -p`.

• To get detailed information about module versions, use the `-p` (Puppetfile) and `--detail` flags. This provides both the expected and actual versions of the modules listed in each environment’s Puppetfile. From the command line, run `r10k deploy display -p --detail`.

• To get detailed information about the modules only in specific environments, limit your query with the environment names. This provides both the expected and actual versions of the modules listed in the Puppetfile in each specified environment. For example, to see details on the modules for environments called `production`, `vmwr`, and `webrefactor`, run:

   ```bash
   r10k deploy display -p --detail production vmwr webrefactor
   ```

### r10k command reference

r10k accepts several command line actions, with options and subcommands.

#### r10k command actions

r10k includes several command line actions.

<table>
<thead>
<tr>
<th>r10k command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>deploy</td>
<td>Performs operations on environments. Accepts <code>deploy</code> subcommands listed below.</td>
</tr>
<tr>
<td>help</td>
<td>Displays the r10k help page in the terminal.</td>
</tr>
<tr>
<td>puppetfile</td>
<td>Performs operations on a Puppetfile. Accepts <code>puppetfile</code> subcommands.</td>
</tr>
<tr>
<td>version</td>
<td>Displays your r10k version in the terminal.</td>
</tr>
</tbody>
</table>

**r10k deploy**

#### r10k command options

r10k commands accept the following options.

<table>
<thead>
<tr>
<th>r10k command options</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>--color</td>
<td>Enables color coded log messages.</td>
</tr>
<tr>
<td>--help, -h</td>
<td>Shows help for this command.</td>
</tr>
<tr>
<td>--trace, -t</td>
<td>Displays stack traces on application crash.</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Sets log verbosity. Valid values: fatal, error, warn, notice, info, debug, debug1, debug2.</td>
</tr>
</tbody>
</table>

#### r10k deploy subcommands

You can use the following subcommands with the `r10k deploy` command.

**r10k deploy --display**

<table>
<thead>
<tr>
<th>deploy subcommand</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>display</td>
<td>Displays a list of environments in your deployment.</td>
</tr>
</tbody>
</table>
### deploy subcommand

<table>
<thead>
<tr>
<th>Action</th>
<th>deploy subcommand</th>
</tr>
</thead>
<tbody>
<tr>
<td>Displays a list of modules in the Puppetfile.</td>
<td>display -p</td>
</tr>
<tr>
<td>Displays detailed information.</td>
<td>display --detail</td>
</tr>
<tr>
<td>Update the environment sources. Allows you to check for missing environments.</td>
<td>display --fetch</td>
</tr>
<tr>
<td>Deploys environments and their specified modules.</td>
<td>environment</td>
</tr>
<tr>
<td>Updates modules specified in the environment’s Puppetfile.</td>
<td>environment -p</td>
</tr>
<tr>
<td>Deploys a module in all environments.</td>
<td>module</td>
</tr>
<tr>
<td>Updates all modules in a particular environment.</td>
<td>module -e</td>
</tr>
<tr>
<td>Prevents the overwriting of local changes to Git-based modules.</td>
<td>no-force</td>
</tr>
</tbody>
</table>

See the related topic about deploying environments with r10k for examples of `r10k deploy` command use.

#### r10k puppetfile subcommands

The `r10k puppetfile` command accepts several subcommands for managing modules.

#### r10k puppetfile install

These subcommands must be run as the user with write access to that environment’s modules directory. These commands interact with the Puppetfile in the current working directory, so before running the subcommand, make sure you are in the directory of the Puppetfile you want to use.

<table>
<thead>
<tr>
<th>Action</th>
<th>puppetfile subcommand</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verifies the Puppetfile syntax is correct.</td>
<td>check</td>
</tr>
<tr>
<td>Installs all modules from a Puppetfile.</td>
<td>install</td>
</tr>
<tr>
<td>Installs modules from a custom Puppetfile path.</td>
<td>install --puppetfile</td>
</tr>
<tr>
<td>Installs modules from a Puppetfile to a custom module directory location.</td>
<td>install --moduledir</td>
</tr>
<tr>
<td>Installs modules from a Puppetfile with a forced overwrite of local changes to Git-based modules.</td>
<td>install --update_force</td>
</tr>
<tr>
<td>Purges unmanaged modules from a Puppetfile managed directory.</td>
<td>purge</td>
</tr>
</tbody>
</table>

### About file sync

File sync helps Code Manager keep your Puppet code synchronized across multiple masters.

When triggered by a web endpoint, file sync takes changes from your working directory on your master and deploys the code to a live code directory. File sync then automatically deploys that code onto all your compilers, ensuring that all masters in a multi-master configuration are kept in sync.

In addition, file sync ensures that your Puppet code is deployed only when it is ready. These deployments ensure that your agents’ code won’t change during a run. File sync also triggers an environment cache flush when the deployment has finished, to ensure that new agent runs happen against the newly deployed Puppet code.
File sync works with Code Manager, so you typically won't need to do anything with file sync directly. If you want to know more about how file sync works, or you need to work with file sync directly for testing, this page provides additional information.

**File sync terms**

There are a few terms that are helpful when you are working with file sync or tools that use file sync.

**Live code directory**

This is the directory that all of the Puppet environments, manifests, and modules are stored in. This directory is used by Puppet Server for catalog compilation. It corresponds to the Puppet Server `master-code-dir` setting and the Puppet `$codedir` setting. The default value is `/etc/puppetlabs/code`. In file sync configuration, you might see this referred to simply as live-dir. This directory exists on all of your masters.

**Staging code directory**

This is the directory where you stage your code changes before rolling them out to the live code dir. You can move files into this directory in your usual way. Then, when you trigger a file sync deployment, file sync moves the changes to the live code dir on all of your masters. This directory exists only on the master; compilers do not need a staging directory. The default value is `/etc/puppetlabs/code-staging`.

**How file sync works**

File sync helps distribute your code to all of your masters and agents.

By default, file sync is disabled and the staging directory is not created on the master. If you're upgrading from 2015.2 or earlier, file sync is disabled after the upgrade. You must enable file sync, and then run Puppet on all masters. This creates the staging directory on the master, which you can then populate with your Puppet code. File sync can then commit your code; that is, it can prepare the code for synchronization to the live code directory, and then your compilers. Normally, Code Manager triggers this commit automatically, but you can trigger a commit by hitting the file sync endpoint.

For example:

**Bash**

```bash
type_header='Content-Type: application/json'
cert="$(puppet config print hostcert)"
cacert="$(puppet config print localcacert)"
key="$(puppet config print hostprivkey)"
uri="https://$(puppet config print server):8140/file-sync/v1/commit"
data='{"commit-all": true}'
curl --header "$type_header" --cert "$cert" --cacert "$cacert" --key "$key" --request POST "$uri" --data "$data"
```

The above command is run from the master and contains the following variables:

- `fqdn`: Fully qualified domain name of the master.
- `cert`: The ssl cert for the master.
- `cacert`: The Puppet CA's certificate.
- `key`: The private key for the master.

This command commits all of the changes in the staging directory. After the commit, when any compilers check the file sync service for changes, they receive the new code and deploy it into their own code directories, where it is available for agents checking in to those masters. (By default, compilers check file sync every 5 seconds.) Commits can be restricted to a specific environment and can include details such as a message, and information about the commit author.
Enabling or disabling file sync

File sync is normally enabled or disabled automatically along with Code Manager.

File sync's behavior is linked to that of Code Manager. Because Code Manager is disabled by default, file sync is also disabled. To enable file sync, enable Code Manager. You can enable and configure Code Manager either during or after PE installation.

The `file_sync_enabled` parameter in the `puppet_enterprise::profile::master` class in the console defaults to `automatic`, which means that file sync is enabled and disabled automatically with Code Manager. If you set this parameter to `true`, it forces file sync to be enabled even if Code Manager is disabled. The `file_sync_enabled` parameter doesn't appear in the class definitions --- you must add the parameter to the class in order to set it.

Resetting file sync

If file sync has entered a failure state, consumed all available disk space, or a repository has become irreparably corrupted, reset the service.

Resetting deletes the commit history for all repositories managed by file sync, which frees up disk space and returns the service to a "fresh install" state while preserving any code in the staging directory.

1. On the master, perform the appropriate action:
   - If you use file sync with Code Manager, ensure that any code ready for deployment is present in the staging directory, and that the code most recently deployed is present in your control repository so that it can be re-synced.
   - If you use file sync with r10k, perform an r10k deploy and ensure that the code most recently deployed is present in your control repository so that it can be re-synced.
   - If you use file sync alone, ensure that any code ready for deployment is present in `/etc/puppetlabs/code-staging`.

2. Shut down the pe-puppetserver service: `puppet resource service pe-puppetserver ensure=stopped`.

3. Delete the data directory located at `/opt/puppetlabs/server/data/puppetserver/filesync/storage`.

4. Restart the pe-puppetserver service: `puppet resource service pe-puppetserver ensure=running`.

5. Perform the appropriate action:
   - If you use file sync with Code Manager, use Code Manager to deploy all environments.
   - If you use file sync alone or with r10k, perform a commit.

File sync is now reset. The service creates fresh repositories on each client and the storage server for the code it manages.

Checking your deployments

You can manually check information about file sync's deployments with curl commands that hit the `status` endpoint.

To manually check that your code has been successfully committed and deployed, you can hit a status endpoint on the master.

**Bash**

```bash
uri="https://$(puppet config print server):8140/status/v1/services?
level=debug"

curl --insecure "$uri"
```

This returns output in JSON, so you can pipe it to `python -m json.tool` for better readability.
To check a list of file sync’s clients, query the `file-sync-storage-service` section of the master by running a curl command.

This command returns a list of:

- All of the clients that file sync is aware of.
- When those clients last checked in.
- Which commit they have deployed.

**Bash**

```bash
uri="https://$(puppet config print server):8140/status/v1/services/file-sync-client-service?level=debug"

curl --insecure "$uri"
```

If your commit has been deployed, it is listed in the status listing for `latest_commit`.

**Cautions**

There are a few things to be aware of with file sync.

**Always use the staging directory**

Always make changes to your Puppet code in the staging directory. If you have edited code in the live code directory on the master or any compiled masters, it’s overwritten by file sync on the next commit.

The `enable-forceful-sync` parameter is set to `true` by default in PE. When `false`, file sync does not overwrite changes in the code directory, but instead logs errors in `/var/log/puppetlabs/puppetserver/puppetserver.log`. To set this parameter to `false`, add via Hiera (puppet_enterprise::master::file_sync::file_sync_enable_forceful_sync: false).

**The puppet module command and file sync**

The `puppet module` command doesn’t work with file sync. If you are using file sync, specify modules in the Puppetfile and use Code Manager to handle your syncs.

**Permissions**

File sync runs as the `pe-puppet` user. To sync files, file sync must have permission to read the staging directory and to write to all files and directories in the live code directory. To make sure file sync can read and write what it needs to, ensure that these code directories are both owned by the `pe-puppet` user:

```
chown -R pe-puppet /etc/puppetlabs/code /etc/puppetlabs/code-staging
```

**Environment isolation metadata**

File sync generates `.pp` metadata files in both your live and staging code directories. These files provide environment isolation for your resource types, ensuring that each environment uses the correct version of the resource type. Do not delete or modify these files. Do not use expressions from these files in regular manifests.

For more details about these files and how they isolate resource types in multiple environments, see environment isolation.
SSL and certificates

Network communications and security in Puppet Enterprise are based on HTTPS, which secures traffic using X.509 certificates. PE includes its own CA tools, which you can use to regenerate certs as needed.

- **Regenerate the console certificate** on page 639  
The console certificate expires every 824 days. Regenerate the console certificate when it's nearing or past expiration, or if the certificate is corrupted and you're unable to access the console.

- **Regenerate infrastructure certificates** on page 639  
Regenerating certificates and security credentials—both private and public keys—created by the built-in PE certificate authority can help ensure the security of your installation in certain cases.

- **Use an independent intermediate certificate authority** on page 642  
The built-in Puppet certificate authority automatically generates a root and intermediate certificate, but you can set up an independent intermediate certificate authority during installation if you need additional intermediate certificates, or if you prefer to use a public authority CA.

- **Use a custom SSL certificate for the console** on page 643  
The console uses a certificate signed by PE's built-in certificate authority (CA). Because this CA is specific to PE, web browsers don't know it or trust it, and you have to add a security exception in order to access the console. You might find that this is not an acceptable scenario and want to use a custom CA to create the console's certificate.

- **Change the hostname of a master** on page 644  
To change the hostnames assigned to your PE infrastructure nodes, you must update the corresponding PE certificate names. You might have to update your master hostname, for example, when migrating to a new PE installation, or after an organizational change such as a change in company name.

- **Generate a custom Diffie-Hellman parameter file** on page 645  
The "Logjam Attack" (CVE-2015-4000) exposed several weaknesses in the Diffie-Hellman (DH) key exchange. To help mitigate the "Logjam Attack," PE ships with a pre-generated 2048 bit Diffie-Hellman param file. In the case that you don't want to use the default DH param file, you can generate your own.

- **Enable TLSv1** on page 646  
TLSv1 and TLSv1.1 are disabled by default in PE.

---

**Regenerate the console certificate**

The console certificate expires every 824 days. Regenerate the console certificate when it's nearing or past expiration, or if the certificate is corrupted and you're unable to access the console.

After you delete the existing console certificate and its artifacts, a new certificate is generated automatically on the next Puppet run.

1. On your master, run:

   ```
   rm /etc/puppetlabs/puppet/ssl/ca/signed/console-cert.pem
   rm /etc/puppetlabs/puppet/ssl/certs/console-cert.pem
   rm /etc/puppetlabs/puppet/ssl/private_keys/console-cert.pem
   rm /etc/puppetlabs/puppet/ssl/public_keys/console-cert.pem
   ```

2. Run Puppet, `puppet agent -t`, or wait for the next Puppet run.

---

**Regenerate infrastructure certificates**

Regenerating certificates and security credentials—both private and public keys—created by the built-in PE certificate authority can help ensure the security of your installation in certain cases.

The process for regenerating certificates varies depending on your goal.
If your goal is to... | Do this...
---|---
Upgrade to the intermediate certificate architecture introduced in Puppet 6.0. | Complete these tasks in order:
Fix a compromised or damaged certificate authority. | 1. Delete and recreate the certificate authority on page 640
2. Regenerate compiler certificates on page 640, if applicable
3. Regenerate agent certificates on page 641
4. Regenerate replica certificates on page 641

Fix a compromised compiler certificate or troubleshoot SSL errors on compilers. | Regenerate compiler certificates on page 640
Fix a compromised agent certificate or troubleshoot SSL errors on agent nodes. | Regenerate agent certificates on page 641 or Regenerate Windows agent certificates
Specify a new DNS alt name or other trusted data. | Regenerate master certificates on page 642

**Note:** To support recovery, backups of your certificates are saved and the location of the backup directory is output to the console. If the command fails after deleting the certificates, you can restore your certificates with the contents of this backup directory.

**Delete and recreate the certificate authority**

Recreate the certificate authority only if you're upgrading to the new certificate architecture introduced in Puppet 6.0, or if your certificate authority was compromised or damaged beyond repair.

**Before you begin**

The `puppet infrastructure run` command leverages built-in Bolt plans to automate certain management tasks. To use this command, you must be able to connect using SSH from your master to any nodes that the command modifies. You can establish an SSH connection using key forwarding, a local key file, or by specifying keys in `.ssh/config` on your master. For more information, see [Bolt OpenSSH configuration options](https://docs.puppet.com/bolt/commands/ssh.html).

⚠️ **CAUTION:** Replacing your certificate authority invalidates all existing certificates in your environment. Complete this task only if and when you're prepared to regenerate certificates for both your infrastructure nodes (including external PE-PostgreSQL in extra-large installations) and your entire agent fleet.

On your master logged in as root, run:

```
puppet infrastructure run rebuild_certificate_authority
```

The SSL and cert directories on your CA server are backed up with "_.bak" appended to the end, CA files are removed and certificates are rebuilt, and a Puppet run completes.

**Regenerate compiler certificates**

Regenerate compiler certificates to fix a compromised certificate or troubleshoot SSL errors on compilers, or if you recreated your certificate authority.

On your master logged in as root, run the following command, specifying any additional parameters required for your environment and use case:

```
puppet infrastructure run regenerate_compiler_certificate
target=<COMPILER_HOSTNAME>
```
• **If you use DNS alternative names**, specify `dns_alt_names` as a comma-separated list of names to add to agent certificates.

**Important:** To ensure naming consistency, if your `puppet.conf` file includes a `dns_alt_names` entry, you must include the `dns_alt_names` parameter and pass in all alternative names included in the entry when regenerating your agent certificates.

• **If you recreated your certificate authority**, or are otherwise unable to connect to the compiler with the orchestrator, specify `clean_crl=true` and `--use-ssh`, as well as any additional parameters needed to connect over SSH.

The compiler's SSL directory is backed up to `/etc/puppetlabs/puppet/ssl_bak`, its certificate is regenerated and signed, a Puppet run completes, and the compiler resumes its role in your deployment.

#### Regenerate agent certificates

Regenerate *nix or Windows agent certificates to fix a compromised certificate or troubleshoot SSL errors on agents, or if you recreated your certificate authority.

On your master logged in as root, run the following command, specifying any additional parameters required for your environment and use case:

```bash
puppet infrastructure run regenerate_agent_certificate
agent=<AGENT_HOSTNAME_1>,<AGENT_HOSTNAME_2>
```

• **If you use DNS alternative names**, specify `dns_alt_names` as a comma-separated list of names to add to agent certificates.

**Important:** To ensure naming consistency, if your `puppet.conf` file includes a `dns_alt_names` entry, you must include the `dns_alt_names` parameter and pass in all alternative names included in the entry when regenerating your agent certificates.

• **If you recreated your certificate authority**, or are otherwise unable to connect to nodes with the orchestrator, specify `clean_crl=true` and `--use-ssh`, as well as any additional parameters needed to connect over SSH.

Agent SSL directories are backed up to `/etc/puppetlabs/puppet/ssl_bak` (*nix) or `C:/ProgramData/PuppetLabs/puppet/etc/ssl_bak` (Windows), their certificates are regenerated and signed, a Puppet run completes, and the agents resume their role in your deployment.

#### Regenerate replica certificates

Regenerate master replica certificates for your disaster recovery installation to specify a new DNS alt name or other trusted data, or if you recreated your certificate authority.

On your master logged in as root, run the following command, specifying any additional parameters required for your environment and use case:

```bash
puppet infrastructure run regenerate_replica_certificate
target=<REPLICA_HOSTNAME>
```

• **If you use DNS alternative names**, specify `dns_alt_names` as a comma-separated list of names to add to agent certificates.

**Important:** To ensure naming consistency, if your `puppet.conf` file includes a `dns_alt_names` entry, you must include the `dns_alt_names` parameter and pass in all alternative names included in the entry when regenerating your agent certificates.

• **If you recreated your certificate authority**, or are otherwise unable to connect to the replica with the orchestrator, specify `clean_crl=true` and `--use-ssh`, as well as any additional parameters needed to connect over SSH.

The replica's SSL directory is backed up to `/etc/puppetlabs/puppet/ssl_bak`, its certificate is regenerated and signed, a Puppet run completes, and the replica resumes its role in your deployment.
Regenerate master certificates

Regenerate master certificates to specify a new DNS alt name or other trusted data. This process regenerates the certificates for all primary infrastructure nodes, including external PE-PostgreSQL in extra-large installations.

Before you begin

The `puppet infrastructure run` command leverages built-in Bolt plans to automate certain management tasks. To use this command, you must be able to connect using SSH from your master to any nodes that the command modifies. You can establish an SSH connection using key forwarding, a local key file, or by specifying keys in `.ssh/config` on your master. For more information, see Bolt OpenSSH configuration options.

To view all available parameters, use the `--help` flag. The logs for all `puppet infrastructure run` Bolt plans are located at `/var/log/puppetlabs/installer/bolt_info.log`.

On your master logged in as root, run:

```
puppet infrastructure run regenerate_master_certificate
```

You can specify these optional parameters:

- `dns_alt_names` – Comma-separated list of alternate DNS names to be added to the certificates generated for your master.

  **Important:** To ensure naming consistency, if your `puppet.conf` file includes a `dns_alt_names` entry, you must include the `dns_alt_names` parameter and pass in all alternative names included in the entry when regenerating your master certificate.

- `tmpdir` — Path to a directory to use for uploading and executing temporary files.

Use an independent intermediate certificate authority

The built-in Puppet certificate authority automatically generates a root and intermediate certificate, but you can set up an independent intermediate certificate authority during installation if you need additional intermediate certificates, or if you prefer to use a public authority CA.

Before you begin

You must have a CA chain, a CRL chain, and a private key. The chains and key file must be PEM encoded and the CRL chain must be ordered from least to most authoritative, with the cert for the CA that you intend to use positioned first in the chain files.
1. Copy your CA chain, CRL chain, and private key to the node where you're installing the master.
   
   **Tip:** Allow access to your private key only from the PE installation process, which runs as root.

2. Follow the instructions to install PE in text mode, adding the `signing_ca` parameter to `pe.conf`.
   
   You must include all three key/value pairs for the `signing_ca` parameter: `bundle`, `crl_chain`, and `private_key`.

   ```json
   {  
     "pe_install::signing_ca": {  
       "bundle": "/root/ca/int_ca_bundle"  
       "crl_chain": "/root/ca/int_crl_chain"  
       "private_key": "/root/ca/int_key"  
     }  
   }
   ```

3. Validate that the CA is working using the standard openssl tools installed with PE.

   ```bash
   openssl x509 -in /etc/puppetlabs/puppet/ssl/ca/signed/<HOSTNAME>.crt -text -noout
   Certificate:
   
   Data:
   
   Version: 3 (0x2)
   Serial Number: 1 (0x1)
   Signature Algorithm: sha256WithRSAEncryption
   Issuer: CN=intermediate-ca
   ```

---

**Use a custom SSL certificate for the console**

The console uses a certificate signed by PE's built-in certificate authority (CA). Because this CA is specific to PE, web browsers don't know it or trust it, and you have to add a security exception in order to access the console. You might find that this is not an acceptable scenario and want to use a custom CA to create the console's certificate.
Before you begin

- You should have a X.509 cert, signed by the custom party CA, in PEM format, with matching private and public keys.
- If your custom cert is issued by an intermediate CA, the CA bundle needs to contain a complete chain, including the applicable root CA.
- The keys and certs used in this procedure must be in PEM format.

1. Retrieve the custom certificate's public and private keys.
2. Move the public key to /etc/puppetlabs/puppet/ssl/certs/console-cert.pem, replacing any existing file named console-cert.pem.
3. Move the private key to /etc/puppetlabs/puppet/ssl/private_keys/console-cert.pem, replacing any existing file named console-cert.pem.
4. Run Puppet: puppet agent -t

You can navigate to your console and see the custom certificate in your browser.

Change the hostname of a master

To change the hostnames assigned to your PE infrastructure nodes, you must update the corresponding PE certificate names. You might have to update your master hostname, for example, when migrating to a new PE installation, or after an organizational change such as a change in company name.

Before you begin

Download and install the puppetlabs-support_tasks module.

Make sure you are using the latest version of the support_tasks module.
Set up RBAC permissions and token authentication for orchestrator tasks. See Setting PE RBAC permissions and token authentication for orchestrator on page 434 for more information.

To update the hostname of your master:

1. On the master, set the new hostname by running the following command:

   hostnamectl set-hostname newhostname.example.com

2. Make sure the `hostname -f` command returns the new fully qualified hostname, and that it resolves to the same IP address as the old hostname, by adding an entry for the new hostname in `/etc/hosts`:

   `<IP address> <newhostname.example.com> <oldhostname.example.com> ...`

3. Run a task for changing the host name against the old certificate name on the master, using one of the following methods:
   - Using Bolt:

     `bolt task run support_tasks::st0263_rename_pe_master -n $(puppet config print certname) --modulepath="/etc/puppetlabs/code/environments/production/modules"

   **Note:** When running the task, Bolt must be using the default SSH transport, rather than the PCP protocol, to avoid errors when services are restarted.
   - Using the command line:

     `puppet task run support_tasks::st0263_rename_pe_master -n $(puppet config print certname)`

The task restarts all Puppet services, which causes a connection error. You can ignore the error while the task continues to run in the background. To check if the task is complete, tail `/var/log/messages`. When the output from the `puppet agent -t` command is displayed in the system log, the task is complete. For example:

```
# tail /var/log/messages
Aug 15 09:08:29 oldhostname systemd: Reloaded pe-orchestration-services Service.
Aug 15 09:08:29 oldhostname puppet-agent[4780]: (/Stage[main]/Puppet_enterprise::Profile::Orchestrator/ Puppet_enterprise::Trapperkeeper::Pe_service[orchestration-services]/ Service[pe-orchestration-services]) Triggered 'refresh' from 1 event
Aug 15 09:08:34 oldhostname puppet-agent[4780]: Applied catalog in 19.16 seconds
```

**Generate a custom Diffie-Hellman parameter file**

The "Logjam Attack" (CVE-2015-4000) exposed several weaknesses in the Diffie-Hellman (DH) key exchange. To help mitigate the "Logjam Attack," PE ships with a pre-generated 2048 bit Diffie-Hellman param file. In the case that you don't want to use the default DH param file, you can generate your own.

**Note:** In the following procedure, `<PROXY-CUSTOM-dhparam>.pem` can be replaced with any file name, except `dhparam_puppetproxy.pem`, as this is the default file name used by PE.
1. On your master, run:

   /opt/puppetlabs/puppet/bin/openssl dhparam -out /etc/puppetlabs/nginx/<PROXY-CUSTOM-dhparam>.pem 2048

   **Note:** After running this command, PE can take several minutes to complete this step.

2. Open your `pe.conf` file (located at `/etc/puppetlabs/enterprise/conf.d/pe.conf`) and add the following parameter and value:

   "puppet_enterprise::profile::console::proxy::dhparam_file": "/etc/puppetlabs/nginx/<PROXY-CUSTOM-dhparam>.pem"

3. Run Puppet: `puppet agent -t`.

---

### Enable TLSv1

TLSv1 and TLSv1.1 are disabled by default in PE.

You must enable TLSv1 to install agents on these platforms:

- AIX
- CentOS 5
- RHEL 5
- SLES 11
- Solaris 10
- Windows Server 2008 R2

To comply with security regulations, PE 2019.1 and later uses only version 1.2 of the Transport Layer Security (TLS) protocol.

1. In the console, click **Node groups > PE Infrastructure**.

2. On the **Configuration data** tab, add the following class, parameter, and value:

<table>
<thead>
<tr>
<th>Class</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>puppet_enterprise::master::puppetserver</td>
<td>ssl_protocols</td>
<td>[&quot;TLSv1&quot;, &quot;TLSv1.1&quot;, &quot;TLSv1.2&quot;]</td>
</tr>
</tbody>
</table>

3. Click **Add data**, and commit changes.

4. Run Puppet on the master.
• Backing up and restoring Puppet Enterprise on page 647
  Keep regular backups of your PE infrastructure. Backups allow you to more easily migrate to a new master, troubleshoot, and quickly recover in the case of system failures.
• Database maintenance on page 652
  You can optimize the Puppet Enterprise (PE) databases to improve performance.

Back up your infrastructure

PE backup creates a copy of your Puppet master, including configuration, certificates, code, and PuppetDB. By default, PE backs up files to /var/puppetlabs/backups and names them with a timestamp. See the backup and restore reference for a complete list of options for customizing your backup.

1. On your master logged in as root, run puppet-backup create --dir=<BACKUP_DIRECTORY>, specifying a separate disk as your backup directory.
   Backup can take up to several hours depending on the size of PuppetDB.
2. Back up the inventory service secret key located at /etc/puppetlabs/orchestration-services/conf.d/secrets/keys.json

   Secure the key as you would any sensitive information.

   ! CAUTION: The backup command does not include the secret key. You must back up this information separately.

   Related information
   Configuration parameters and the pe.conf file on page 97
   A pe.conf file is a HOCON formatted file that declares parameters and values used to install, upgrade, or configure PE. A default pe.conf file is available in the conf.d directory in the installer tarball.

   Restore your infrastructure

   Use the restore commands to migrate your PE master to a new host or to recover from system failure.

   Before you begin

   Remember that you must restore files to a fresh installation of the same version of PE used in your backup file.

   1. If you are restoring to an existing master, purge any existing PE installation from it.
   a) On the master, uninstall PE by running sudo /opt/puppetlabs/bin/puppet-enterprise-uninstaller -p -d
   b) Ensure that the directories /opt/puppetlabs/ and /etc/puppetlabs/ are no longer present on the system.

       For details about uninstalling PE, see the uninstalling documentation.

   2. Install PE on the master you are restoring to. This must be the same PE version that was used for the backup files.
   a) If you don't have the PE installer script on the machine you want to restore to, download the installer tarball to the machine from the download site, and unpack it by running tar -xf <TARBALL_FILENAME>
   b) Navigate to the directory containing the install script. The installer script is located in the PE directory created when you unpacked the tarball.
   c) Install PE by running sudo ./puppet-enterprise-installer

       For details about the PE installation process, see the installing documentation.

   3. On the master logged in as root, restore your PE infrastructure by running puppet-backup restore <BACKUP-FILENAME>

       To change the default command behavior, pass option flags and values to the command. See the command reference for a complete list of options.

       For example, to restore your scope, certificates, and code from one backup file, but your PuppetDB data from another, pass the --scope option:

           puppet-backup restore pe_backup-2018-03-03_20.07.15_UTC.tgz --scope=config,certs,code

           puppet-backup restore pe_backup-2018-04-04_20.07.15_UTC.tgz --scope=puppetdb

   4. Restore your backup of the secret key used to encrypt and decrypt sensitive data stored in the inventory service.

       The secret key is stored at: /etc/puppetlabs/orchestration-services/conf.d/secrets/keys.json

       ! CAUTION: The restore command does not include the secret key. You must restore this information separately.

   5. Ensure the secret key ownership is pe-orchestration-services:pe-orchestration-services.

   6. Restart the pe-orchestration-services service.
7. If you restored PE onto a master with a different hostname than the original installation, and you have not configured the `dns_alt_names` setting in the `pe.conf` file, redirect your agents to the new master. An easy way to do this is by running a task with the Bolt task runner.
   a) Download and install Bolt, if you don't already have it installed.
   b) Update the `pe.conf` file to point all agents at the new master by running:

   ```bash
   bolt task run puppet_conf action=set section=agent setting=server value=<RESTORE_HOSTNAME> --nodes <COMMA-SEPARATED LIST OF NODES>
   bolt task run puppet_conf action=set section=main setting=server value=<RESTORE_HOSTNAME> --nodes <COMMA-SEPARATED LIST OF NODES>
   
   c) Run `puppet agent -t --no-use_cached_catalog` on the newly restored master **twice** to apply changes and then restart services.
   d) Run `puppet agent -t --no-use_cached_catalog` on all agent nodes to test connection to the new master.

8. If your infrastructure had Code Manager enabled when your backup file was created, deploy your code by running:

   ```bash
   puppet-access login
   puppet code deploy --all --wait
   ```

**Related information**

**Configuration parameters and the `pe.conf` file** on page 97

A `pe.conf` file is a HOCON formatted file that declares parameters and values used to install, upgrade, or configure PE. A default `pe.conf` file is available in the `conf.d` directory in the installer tarball.

**Installing Puppet Enterprise** on page 95

Installing PE begins with setting up a standard installation: a master, console, and PuppetDB operating on a single node. From here, you can scale up to the large or extra-large installation as your infrastructure grows, or customize configuration as needed.

**Uninstalling** on page 136

Puppet Enterprise includes a script for uninstalling. You can uninstall component infrastructure nodes or from agent nodes.

**Backup and restore reference**

Use these options to change the backup and restore scope and other options for the `puppet-backup` command.

**Note:** Backup commands must be run as root.

**puppet-backup create**

Run the `puppet-backup create` command to create backup files of your PE infrastructure.

**Usage:**

```bash
puppet-backup create [--dir=<DIRECTORY_PATH>] [--name=<BACKUP_NAME>.tgz] [--scope=<SCOPE_LIST>] [--force]
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>--dir=BACKUP_DIR</td>
<td>Specifies the directory to write the backup file to.</td>
<td>A valid filepath that the <code>pe-postgres</code> user has write permission for.</td>
<td><code>/var/puppetlabs/backups/</code></td>
</tr>
<tr>
<td>--name=BACKUP_NAME.tgz</td>
<td>Specifies the name for the backup file.</td>
<td>A string designating a filename.</td>
<td><code>pe_backup-&lt;TIMESTAMP&gt;.tgz</code></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Values</td>
<td>Default</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>--pe-environment=ENVIRONMENT</td>
<td>Specifies the environment to backup. To ensure configuration is recovered correctly, this must be the environment where your master is located.</td>
<td>A valid environment name.</td>
<td>production</td>
</tr>
<tr>
<td>--scope=SCOPE</td>
<td>Scope of backup to create.</td>
<td>Either all or any combination of the other available scopes, as a comma-separated list:</td>
<td>all</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• config: PE configuration including license, classification, and RBAC settings. Does not include Puppet gems or Puppet Server gems.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• certs: PE CA certificates and full SSL directory</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• code: Puppet code deployed to your codedir at backup time.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• puppetdb: PuppetDB data, including facts, catalogs, and historical reports</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• all: All listed scopes.</td>
<td></td>
</tr>
<tr>
<td>--force</td>
<td>Bypass validation checks and ignore warnings.</td>
<td>None.</td>
<td>If you don't specify --force, PE verifies that the destination directory exists and has enough space for the backup process.</td>
</tr>
</tbody>
</table>

For example, to create a backup of PuppetDB only and give it a name that shows the scope of the file:

```
puppet-backup create --scope=puppetdb --name=puppetdb_backup_03032018.tgz
```

**puppet-backup restore**

Run the **puppet-backup restore** command to restore your PE infrastructure from backup files.

Usage:

```
puppet-backup restore <PATH/TO/BACKUP_FILE.tgz> [--scope=<SCOPE_LIST>] [--force]
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>--pe-environment=ENVIRONMENT</td>
<td>Specifies the environment to restore.</td>
<td>A valid environment name for which you have an existing backup.</td>
<td>production</td>
</tr>
</tbody>
</table>

© 2020 Puppet, Inc.
**Option**  | **Description**                                                                 | **Values**                                                                                                    | **Default** |
---|---|---|---|
--scope=SCOPE | Scope of backup to restore. All scopes must eventually be restored, but you can restore different scopes from different backup files with successive restore commands. | Either all or any combination of the other available scopes, as a comma-separated list:  
  - `config`: PE configuration including license, classification, and RBAC settings. Does not include Puppet gems or Puppet Server gems.  
  - `certs`: PE CA certificates and full SSL directory  
  - `code`: Puppet code deployed to your codedir at backup time.  
  - `puppetdb`: PuppetDB data, including facts, catalogs, and historical reports  
  - `all`: All listed scopes. | all |
--force | Bypass validation checks and ignore warnings. | None. | If you don’t specify --force, PE verifies that the destination directory exists and has enough space for the restore process. Returns warnings for insufficient space or invalid locations. |

For example, to restore PuppetDB from one backup file and restore configuration, certificates, and code from another backup file:

```
puppet-backup restore /mybackups/pe_backup_03032018.tgz --scope=puppetdb
puppet-backup restore /mybackups/pe_backup_04042018.tgz --scope=config,certs,code
```

### puppetdb

| PuppetDB                          |
| `/opt/puppetlabs/server/data/puppetdb` |

### Database maintenance

You can optimize the Puppet Enterprise (PE) databases to improve performance.

### Databases in Puppet Enterprise

PE uses PostgreSQL as the backend for its databases. Use the native tools in PostgreSQL to perform database exports and imports.

The PE PostgreSQL database includes the following databases:

<table>
<thead>
<tr>
<th>Database</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pe-activity</td>
<td>Activity data from the Classifier, including user, nodes, and time of activity.</td>
</tr>
<tr>
<td>pe-classifier</td>
<td>Classification data, all node group information.</td>
</tr>
<tr>
<td>pe-puppetdb</td>
<td>PuppetDB data, including exported resources, catalogs, facts, and reports.</td>
</tr>
</tbody>
</table>
List all database names

Use these instructions to list all database names.

To generate a list of database names:

1. Assume the pe-postgres user:

   ```
   sudo su - pe-postgres -s /bin/bash
   ```

2. Open the PostgreSQL command-line:

   ```
   /opt/puppetlabs/server/bin/psql
   ```

3. List the databases:

   ```
   \l
   ```

4. Exit the PostgreSQL command line:

   ```
   \q
   ```

5. Log out of the pe-postgres user:

   ```
   logout
   ```

Troubleshooting

Use this guide to troubleshoot issues with your Puppet Enterprise installation.

- Troubleshooting installation on page 654
  If installation fails, check for these issues.
- Troubleshooting disaster recovery on page 654
  If disaster recovery commands fail, check for these issues.
- Troubleshooting puppet infrastructure run commands on page 655
  If puppet infrastructure run commands fail, review the logs at /var/log/puppetlabs/installer/bolt_info.log and check for these issues.
- Troubleshooting connections between components on page 656
  If agent nodes can't retrieve configurations, check for communication, certificate, DNS, and NTP issues.
- Troubleshooting the databases on page 657
  If you have issues with the databases that support the console, make sure that the PostgreSQL database is not too large or using too much memory, that you don't have port conflicts, and that puppet apply is configured correctly.
- Troubleshooting backup and restore on page 658
  If backup or restore fails, check for these issues.
Troubleshooting Windows on page 659
Troubleshoot Windows issues with failed installations and upgrades, and failed or incorrectly applied manifests. Use the error message reference to solve your issues. Enable debugging.

**Troubleshooting installation**
If installation fails, check for these issues.

**Note:** If you encounter errors during installation, you can troubleshoot and run the installer as many times as needed.

**DNS is misconfigured**
DNS must be configured correctly for successful installation.
1. Verify that agents can reach the master hostname you chose during installation.
2. Verify that the master can reach itself at the master hostname you chose during installation.
3. If the master and console components are on different servers, verify that they can communicate with each other.

**Security settings are misconfigured**
Firewall and security settings must be configured correctly for successful installation.
1. On your master, verify that inbound traffic is allowed on ports 8140, 61613, and 443.
2. If your master has multiple network interfaces, verify that the master allows traffic via the IP address that its valid DNS names resolve to, not just via an internal interface.

**Troubleshooting disaster recovery**
If disaster recovery commands fail, check for these issues.

**Latency over WAN**
If the master and replica communicate over a slow, high latency, or lossy connection, the provision and enable commands can fail.

If this happens, try re-running the command.

**Replica is connected to a compiler instead of a master**
The provision command triggers an error if you try to provision a replica node that's connected to a compiler. The error is similar to the following:

```
Failure during provision command during the puppet agent run on replica 2:
Failed to generate additional resources using 'eval_generate':
  Error 500 on SERVER: Server Error: Not authorized to call search on /file_metadata/pe_modules with
  {:rest=>"pe_modules", :links=>"manage", :recurse=>true, :source_permissions=>"ignore", :source=>"pe_modules", :checksum_type=>"md5"
  Source: /Stage[main]/Puppet_enterprise::Profile::Primary_master_replica/ File[/opt/puppetlabs/server/shareinstaller/modules]File: /opt/puppetlabs/puppet/modules/puppet_enterprise/manifests/profile/primary_master_replica.ppLine: 64
```

On the replica you want to provision, edit /etc/puppetlabs/puppet.conf so that the server and server_list settings use a master, rather than a compiler.
**Both server and server_list are set in the agent configuration file**

When the agent configuration file contains settings for both `server` and `server_list`, a warning appears. This warning can occur after enabling a replica. You can ignore the warning, or hide it by removing the `server` setting from the agent configuration, leaving only `server_list`.

**Node groups are empty**

When provisioning and enabling a replica, the orchestrator is used to run Puppet on different groups of nodes. If a group of nodes is empty, the tool reports that there's nothing for it to do and the job is marked as failed in the output of `puppet job show`. This is expected, and doesn't indicate a problem.

---

**Troubleshooting puppet infrastructure run commands**

If `puppet infrastructure run` commands fail, review the logs at `/var/log/puppetlabs/installer/bolt_info.log` and check for these issues.

**Running commands when logged in as a non-root user**

All `puppet infrastructure run` commands require you to act as the root user on all nodes that the command touches. If you are trying to run a `puppet infrastructure run` command as a non-root user, you must be able to SSH to the impacted nodes (as the same non-root user) in order for the command to succeed.

When you run a `puppet infrastructure run` command, Bolt uses your system's existing OpenSSH `ssh_config` configuration file to connect to your nodes. If this file is missing or configured incorrectly, Bolt tries to connect as root. To make sure the correct user connects to the nodes, you have the following options.

1. Set up your OpenSSH `ssh_config` configuration file to point to a user with sudo privileges:

   ```
   Host *.example.net
   UserKnownHostsFile=~/.ssh/known_hosts
   User <USER WITH SUDO PRIVILEGES>
   ```

2. When running a `puppet infrastructure run` command, pass in the `--user <USER WITH SUDO PRIVILEGES>` flag.

   If your sudo configuration requires a password to run commands, pass in the `--sudo-password <PASSWORD>` flag when running a `puppet infrastructure run` command.

   **Note:** To avoid logging your password to `.bash_history`, set `HISTCONTROL=ignore_space` in your `.bashrc` file and add a space to the beginning of the command.

   If your operating system distribution includes the `requiretty` option in its `/etc/sudoers` file, you must either remove this option from the file or pass the `--tty` flag when running a `puppet infrastructure run` command.

**Passing hashes from the command line**

When passing a hash on the command line as part of a `puppet infrastructure run` command, the hash must be quoted, much like a JSON object. For example:

```
'{"parameter_one": "value_one", "parameter_two": "value_two"}'
```
Troubleshooting connections between components

If agent nodes can't retrieve configurations, check for communication, certificate, DNS, and NTP issues.

Agents can’t reach the Puppet master

Agent nodes must be able to communicate with the Puppet master in order to retrieve configurations.

If agents can't reach the Puppet master, running `telnet <puppet master's hostname> 8140` returns the error "Name or service not known."

1. Verify that the Puppet master server is reachable at a DNS name your agents recognize.
2. Verify that the `pe-puppetserver` service is running.

Agents don’t have signed certificates

Agent certificates must be signed by the Puppet master.

If the node's Puppet agent logs have a warning about unverified peer certificates in the current SSL session, the agent has submitted a certificate signing request that hasn't yet been signed.

1. On the master, view a list of pending certificate requests: `puppet cert list`
2. Sign a specified node's certificate: `puppetserver ca sign <NODE NAME>`

Agents aren’t using the master’s valid DNS name

Agents trust the master only if they contact it at one of the valid hostnames specified when the master was installed.

On the node, if the results of `puppet agent --configprint server` don't return one of the valid DNS names you chose during installation of the master, the node and master can’t establish communication.

1. To edit the master's hostname on nodes, in `/etc/puppetlabs/puppet/puppet.conf`, change the `server` setting to a valid DNS name.
2. To reset the master's valid DNS names, run:

```
/etc/init.d/pe-nginx stop
puppet cert clean <MASTER_CERTNAME>
puppet cert generate <MASTER_CERTNAME> --dns_alt_names=<COMMA-SEPARATED_LIST_OF_DNS_NAMES>
/etc/init.d/pe-nginx start
```

Time is out of sync

The date and time must be in sync on the Puppet master and agent nodes.

If time is out of sync on nodes, running `date` returns incorrect or inconsistent dates.

Get time in sync by setting up NTP. Keep in mind that NTP can behave unreliably on virtual machines.

Node certificates have invalid dates

The date and time must be in sync when certificates are created.

If certificates were signed out of sync, running `openssl x509 -text -noout -in $(puppet config print --section master ssldir)/certs/<NODE NAME>.pem` returns invalid dates, such as certificates dated in the future.

1. On the master, delete certificates with invalid dates: `puppet cert clean <NODE NAME>`
2. On nodes with invalid certificates, delete the SSL directory: `rm -r $(puppet config print --section master ssldir)
3. On agent nodes, generate a new certificate request: `puppet agent --test`
4. On the master, sign the request: `puppetserver ca sign <NODE NAME>`
A node is re-using a certname

If a node re-uses an old node's certname and the master retains the previous node's certificate, the new node is unable to request a new certificate.

1. On the master, clear the node's certificate: `puppetserver ca clean <NODE_NAME>`
2. On agent node, generate a new certificate request: `puppet agent --test`
3. On the master, sign the request: `puppetserver ca sign <NODE_NAME>`

Agents can't reach the filebucket server

If the master is installed with a certname that doesn't match its hostname, agents can't back up files to the filebucket on the Puppet master.

If agents log errors like "could not back up," nodes are likely attempting to back up files to the wrong hostname.

On the master, edit `/etc/puppetlabs/code/environments/production/manifests/site.pp` so that filebucket server attribute points to the correct hostname:

```puppet
# Define filebucket 'main':
filebucket { 'main':
    server => '<PUPPET_MASTER_DNS_NAME>',
    path   => false,
}
```

Changing the filebucket server attribute on the master fixes the error on all agent nodes.

Orchestrator can't connect to PE Bolt server

Debug a faulty connection between the orchestrator and PE Bolt server by setting the `bolt_server_loglevel` in the `puppet_enterprise::profile::bolt_server` class and running Puppet, or by manually updating `loglevel` in `/etc/puppetlabs/bolt-server/conf.d/bolt-server.conf`. The server logs are located at `/var/log/puppetlabs/bolt-server/bolt-server.log`.

Troubleshooting the databases

If you have issues with the databases that support the console, make sure that the PostgreSQL database is not too large or using too much memory, that you don't have port conflicts, and that `puppet apply` is configured correctly.

**Note:** If you're using your own instance of PostgreSQL for the console and PuppetDB, you must use version 9.1 or higher.

PostgreSQL is taking up too much space

The PostgreSQL `autovacuum=on` setting prevents the database from growing too large and unwieldy. Routine vacuuming is turned on by default.

Verify that `autovacuum` is set to `on`.

PostgreSQL buffer memory causes installation to fail

When installing PE on machines with large amounts of RAM, the PostgreSQL database might use more shared buffer memory than is available.

If this issue is present, `/var/log/pe-postgresql/pgstartup.log` shows the error:

```
FATAL: could not create shared memory segment: No space left on device
DETAIL: Failed system call was shmget(key=5432001, size=34427584512,03600).
```

1. On the master, set the `shmmax` kernel setting to approximately 50% of the total RAM.

© 2020 Puppet, Inc.
2. Set the shmall kernel setting to the quotient of the new shmmax setting divided by the page size. You can confirm page size by running `getconf PAGE_SIZE`.

3. Set the new kernel settings:

   ```bash
   sysctl -w kernel.shmmax=<your shmmax calculation>
   sysctl -w kernel.shmall=<your shmall calculation>
   ```

**The default port for PuppetDB conflicts with another service**

By default, PuppetDB communicates over port 8081. In some cases, this might conflict with existing services, for example McAfee ePolicy Orchestrator.

Install in text mode with a parameter in `pe.conf` that specifies a different port using `puppet_enterprise::puppetdb_port`.

**puppet resource generates Ruby errors after connecting puppet apply to PuppetDB**

If Puppet apply is configured incorrectly, for example by modifying `puppet.conf` to add the parameters `storeconfigs_backend = puppetdb` and `storeconfigs = true` in both the main and master sections, `puppet resource` ceases to function and displays a Ruby run error.

Modify `/etc/puppetlabs/puppet/routes.yaml` to correctly connect Puppet apply without affecting other functions.

**Troubleshooting backup and restore**

If backup or restore fails, check for these issues.

**The puppet-backup restore command fails with errors about a duplicate operator family**

When restoring the `pe-rbac` database, the restore process exits with errors about a duplicate operator family, `citext_ops`.

To work around this issue:

1. Log into your PostgreSQL instance:

   ```bash
   sudo su - pe-postgres -s /bin/bash -c "/opt/puppetlabs/server/bin/psql pe-rbac"
   ```

2. Run these commands:

   ```sql
   ALTER EXTENSION citext ADD operator family citext_ops using btree;
   ALTER EXTENSION citext ADD operator family citext_ops using hash;
   ```

3. Exit the PostgreSQL shell and re-run the backup utility.
Troubleshooting Windows

Troubleshoot Windows issues with failed installations and upgrades, and failed or incorrectly applied manifests. Use the error message reference to solve your issues. Enable debugging.

Installation fails
Check for these issues if Windows installation with Puppet fails.

The installation package isn't accessible
The source of an MSI or EXE package must be a file on either a local filesystem, a network mapped drive, or a UNC path.

RI-based installation sources aren't supported, but you can achieve a similar result by defining a file whose source is the Puppet master and then defining a package whose source is the local file.

Installation wasn’t attempted with admin privileges
Puppet fails to install when trying to perform an unattended installation from the command line. A "norestart" message is returned, and installation logs indicate that installation is forbidden by system policy.

You must install as an administrator.

Upgrade fails
The Puppet MSI package overwrites existing entries in the puppet.conf file. If you upgrade or reinstall using a different master hostname, Puppet applies the new value in $confdir\puppet.conf.

When you upgrade Windows, you must use the same master hostname that you specified when you installed.

For information on what settings are preserved during an upgrade, see installing Install Windows agents on page 113.

Errors when applying a manifest or doing a Puppet agent run
Check for the following issues if manifests cannot be applied or are not applied correctly on Windows nodes.

Path or file separators are incorrect
For Windows, path separators must use a semi-colon (;), while file separators must use forward or backslashes as appropriate to the attribute.

In most resource attributes, the Puppet language accepts either forward or backslashes as the file separator. However, some attributes absolutely require forward slashes, and some attributes absolutely require backslashes.

When backslashes are double-quoted("), they must be escaped. When single-quoted ('), they can be escaped. For example, these are valid file resources:

```puppet
file { 'c:\path\to\file.txt': }  
file { 'c:\\path\\to\\file.txt': }  
file { "c:\\path\\to\file.txt": }  
```

But this is an invalid path, because \p, \t, and \f are interpreted as escape sequences:

```puppet
file { "c:\path\to\file.txt": }  
```

For more information, see the language reference about backslashes on Windows.
Cases are inconsistent
Several resources are case-insensitive on Windows, like files, users, groups. However, these resources can be case sensitive in Puppet.

When establishing dependencies among resources, make sure to specify the case consistently. Otherwise, Puppet can’t resolve dependencies correctly. For example, applying this manifest fails, because Puppet doesn’t recognize that ALEX and alex are the same user:

```puppet
file { 'c:\foo\bar':
  ensure => directory,
  owner  => 'ALEX'
}
user { 'alex':
  ensure => present
}
...
err: /Stage[main]//File[c:\foo\bar]: Could not evaluate: Could not find user ALEX
```

Shell built-ins are not executed
Puppet doesn’t support a shell provider on Windows, so executing shell built-ins directly fails.

Wrap the built-in in `cmd.exe`:

```puppet
eexec { 'cmd.exe /c echo foo':
  path => 'c:\windows\system32;c:\windows'
}
```

Tip: In the 32-bit versions of Puppet, you might encounter file system redirection, where system32 is switched to sysWoW64 automatically.

PowerShell scripts are not executed
By default, PowerShell enforces a restricted execution policy which prevents the execution of scripts.

Specify the appropriate execution policy in the PowerShell command, for example:

```puppet
eexec { 'test':
  command => 'powershell.exe -executionpolicy remotesigning -file C:\test.ps1',
  path => $::path
}
```

Or use the Puppet supported PowerShell.

Services are referenced with display names instead of short names
Windows services support a short name and a display name, but Puppet uses only short names.

1. Verify that your Puppet manifests use short names, for example `wuauserv`, not `Automatic Updates`.
**Error messages**

Use this reference to troubleshoot error messages when using Windows with Puppet.

- **Error: Could not connect via HTTPS to https://forge.puppet.com / Unable to verify the SSL certificate / The certificate may not be signed by a valid CA / The CA bundle included with OpenSSL may not be valid or up to date**

  This error occurs when you run the puppet module subcommand on newly provisioned Windows nodes. The Forge uses an SSL certificate signed by the GeoTrust Global CA certificate. Newly provisioned Windows nodes might not have that CA in their root CA store yet.

  Download the "GeoTrust Global CA" certificate from GeoTrust's list of root certificates and manually install it by running `certutil -addstore Root GeoTrust_Global_CA.pem`.

- **Service 'Puppet Agent' (puppet) failed to start. Verify that you have sufficient privileges to start system services.**

  This error occurs when installing Puppet on a UAC system from a non-elevated account. Although the installer displays the UAC prompt to install Puppet, it does not elevate privileges when trying to start the service.

  Run from an elevated `cmd.exe` process when installing the MSI.

- **Cannot run on Microsoft Windows without the sys-admin, win32-process, win32-dir, win32-service and win32-taskscheduler gems.**

  This error occurs if you attempt to run Windows without required gems.

  Install specified gems: `gem install <GEM_NAME>`

- **"err: /Stage[main]//Scheduled_task[task_system]: Could not evaluate: The operation completed successfully."**

  This error occurs when using a the task scheduler gem earlier than version 0.2.1.

  Update the task scheduling gem: `gem update win32-taskscheduler`

- **err: /Stage[main]//Exec[C:/tmp/foo.exe]/returns: change from notrun to 0 failed: CreateProcess() failed: Access is denied.**

  This error occurs when requesting an executable from a remote Puppet master that cannot be executed.

  Set the user/group executable bits appropriately on the master:

  ```
  file { "C:/tmp/foo.exe":
    source => "puppet:///modules/foo/foo.exe",
  }
  
  exec { 'C:/tmp/foo.exe':
    logoutput => true
  }
  ```

- **err: getaddrinfo: The storage control blocks were destroyed.**

  This error occurs when the agent can't resolve a DNS name into an IP address or if the reverse DNS entry for the agent is wrong.

  Verify that you can run `nslookup <dns>`. If this fails, there is a problem with the DNS settings on the Windows agent, for example, the primary dns suffix is not set. For more information, see [Microsoft's documentation on Naming Hosts and Domains](#).

- **err: Could not request certificate: The certificate retrieved from the master does not match the agent's private key.**

  This error occurs if the agent's SSL directory is deleted after it retrieves a certificate from the master, or when running the agent in two different security contexts.

  Elevate privileges using **Run as Administrator** when you select **Start Command Prompt with Puppet**.
• **err:** Could not send report: SSL_connect returned=1 errno=0 state=SSLv3 read server certificate B: certificate verify failed. This is often because the time is out of sync on the server or client.

This error occurs when Windows agents' time isn't synched. Windows agents that are part of an Active Directory domain automatically have their time synchronized with AD.

For agents that are not part of an AD domain, enable and add the Windows time service manually:

```
  w32tm /register  
  net start w32time  
  w32tm /config /manualpeerlist:<ntpserver> /syncfromflags:manual /update  
  w32tm /resync
```

• **Error:** Could not parse for environment production: Syntax error at '='; expected ')

This error occurs if `puppet apply -e` is used from the command line and the supplied command is surrounded with single quotes ('), which causes cmd.exe to interpret any `=>` in the command as a redirect.

Surround the command with double quotes ("), instead.

**Logging and debugging**

The Windows Event Log can be helpful when troubleshooting issues with Windows.

Enable Puppet to emit `--debug` and `--trace` messages to the Windows Event Log by stopping the Puppet service and restarting it:

```
c:\>sc stop puppet && sc start puppet --debug --trace
```

Note that this setting takes effect only until the next time the service is restarted, or until the system is rebooted.
